THE NUMBER OF INTERVALS IN THE $m$-TAMARI LATTICES

MIREILLE BOUSQUET-MÉLOU, ÉRI FUSY, AND LOUIS-FRANÇOIS PRÉVILE-RATELLE

Abstract. An $m$-ballot path of size $n$ is a path on the square grid consisting of north and east steps, starting at $(0,0)$, ending at $(mn,n)$, and never going below the line $\{x=my\}$. The set of these paths can be equipped with a lattice structure, called the $m$-Tamari lattice and denoted by $T_n(m)$, which generalizes the usual Tamari lattice $T_n$ obtained when $m=1$. We prove that the number of intervals in this lattice is

$$\frac{m+1}{n(mn+1)} \binom{(m+1)^2n+m}{n-1}.$$ 

This formula was recently conjectured by Bergeon in connection with the study of coinvariant spaces. The case $m=1$ was proved a few years ago by Hapoton. Our proof is based on a recursive description of intervals, which translates into a functional equation satisfied by the associated generating function. The solution of this equation is an algebraic series, obtained by a guess-and-check approach. Finding a bijective proof remains an open problem.

1. Introduction

A ballot path of size $n$ is a path on the square lattice, consisting of north and east steps, starting at $(0,0)$, ending at $(n,n)$, and never going below the line $\{x=y\}$. There are three standard ways, often named after Stanley, Kreweras and Tamari, to endow the set of ballot paths of size $n$ with a lattice structure (see [14, 17, 19], and [4] or [18] for a survey). We focus on the Tamari lattice $T_n$, which, as detailed in the following proposition, is conveniently described by the associated covering relation. See Figure 1 for an illustration.

![Diagram of ballot paths](image)

Figure 1. A covering relation in the Tamari lattice, own on ballot paths and binary trees. The path encodes the postorder of the tree.
Proposition 1. [4, Prop. 2.1] Let $P$ and $Q$ be two ballot paths of size $n$. Then $Q$ covers $P$ in the Tamari lattice $T_n$ if and only if there exists in $P$ an east step $a$, followed by a north step $b$, such that $Q$ is obtained from $P$ by swapping $a$ and $S$, where $S$ is the shortest factor of $P$ that begins with $b$ and is a (translated) ballot path.

Alternatively, the Tamari lattice $T_n$ is often described in terms of rooted binary trees. The covering relation amounts to a re-organization of the tree subtrees, often called rotation (Figure 1). The equivalence between the two descriptions is obtained by reading the tree in postorder, and encoding each leaf (resp. inner node) by a north (resp. east) step (apart from the first leaf, which is not encoded). We refer to [4, Sec. 2] for details. The Hasse diagram of the lattice $T_n$ is the 1-skeleton of the associahedron, or Stasheff polytope [10].

A few years ago, Chapoton [11] proved that the number of intervals in $T_n$ (i.e., pairs $P, Q \in T_n$ such that $P \preceq Q$) is

$$\frac{2}{n(n+1)} \binom{4n+1}{n-1}.$$

This number is known to count 3-connected planar triangulations on $n+3$ vertices [27]. Motivated by this result, Bernardi and Bonic found a beautiful bijection between Tamari intervals and triangulations [4]. The bijection is in fact a restriction of a more general bijection between intervals in the Stanley lattice and Schnyder woods. A further restriction leads to the enumeration of intervals of the Kreweras lattice.

![Figure 2. The relation $\prec$ between $m$-ballot paths ($m = 2$).](image)

In this paper, we study a generalization of the Tamari lattices to $m$ ballot paths due to Bergeron, and count the intervals of these lattices. Again, a remarkably simple formula holds (see (1)). As we explain below, this formula was first conjectured by F. Bergeron, in connection with the study of coinvolution spaces.

An $m$ ballot path of size $n$ is a path on the square grid consisting of north and east steps, starting at $(0,0)$, ending at $(mn,n)$, and never going below the line $\{x = my\}$. It is a classical exercise to show that there are $\frac{1}{mn+1} \binom{(m+1)n}{n}$ such paths [13]. Consider the following relation $\prec$ on $m$-ballot paths, illustrated in Figure 2.

**Definition 2.** Let $P$ and $Q$ be two $m$ ballot paths of size $n$. Then $P \prec Q$ if there exists in $P$ an east step $a$, followed by a north step $b$, such that $Q$ is obtained from $P$ by swapping $a$ and $S$, where $S$ is the shortest factor of $P$ that begins with $b$ and is a (translated) $m$ ballot path.

As we see all, the transitive closure of $\prec$ defines a lattice on $m$-ballot paths of size $n$. We call it the $m$-Tamari lattice of size $n$, and denote it by $T_n^{(m)}$. Of course, $T_n^{(1)}$ coincides with $T_n$. See Figure 3 for examples. The main result of this paper is a closed form expression for the number $f_n^{(m)}$ of intervals in $T_n^{(m)}$:

$$f_n^{(m)} = \frac{m+1}{n(mn+1)} \binom{(m+1)^2 n + m}{n-1}.$$  \hspace{2cm} (1)

The first step of our proof establishes that $T_n^{(m)}$ is in fact isomorphic to a sublattice (and more precisely, an upper ideal) of $T_{mn}$. We then proceed with a recursive description of the intervals.
Figure 3. The $m$-Tamari lattice $\mathcal{T}_n^{(m)}$ for $m = 1$ and $n = 4$ (left) and for $m = 2$ and $n = 3$ (right). These walks surrounded by a line in $\mathcal{T}_4^{(1)}$ form a lattice that is isomorphic to $\mathcal{T}_2^{(2)}$. This will be generalized in Section 2.
of $T_n^{(m)}$, which translates into a functional equation for the associated generating function (Section 2, Proposition 8). $T$ is a generating function that keeps track of the size of the pattern's number of contacts of the lower pattern with the pattern $\{x = my\}$. A general theorem asserts that the solution of the equation is algebraic [6], and gives a systematic procedure to solve it for small values of $m$. However, for a generic value of $m$, we have to resort to a guess-and-check approach to solve the equation (Section 3, Theorem 10). We enclose the enumeration by taking into account the initial rise of the upper pattern, $t$ at is, the length of its initial run of not steps. We obtain an unexpected symmetry result: the joint distribution of the number of contacts of the lower pattern (minus one) and the initial rise of the upper pattern is symmetric. Section 4 presents comments and questions.

To conclude this introduction, we describe the algebraic problem that led Bergeron to conjecture (1).

Let $X = (x_{i,j})_{1 \leq i,j \leq n}$ be a matrix of variables, for some positive integers $\ell, n \geq 1$. We call each line of $X$ a set of variables. Let $S_n$ be the symmetric group on $n$ elements. $T$ is a group acting as a representation on the polynomials of $\mathbb{C}[X]$ by permuting the columns of $X$. At is, if $\sigma \in S_n$ and $f(X) \in \mathbb{C}[X]$, then

$$\sigma(f(X)) = f((x_{i,j}^{\sigma})_{1 \leq i,j \leq n}).$$

We consider the ideal $I$ of $\mathbb{C}[X]$ generated by $S_n$-invariant polynomials having no constant term. The quotient ring $\mathbb{C}[X]/I$ is (multi-)graded because $I$ is (multi-)homogeneous, and is a representation of $S_n$ because $I$ is invariant under the action of $S_n$. We focus on the dimension of $I$, and to the dimension of the sign subrepresentation. We denote by $W^\varepsilon$ the sign subrepresentation of a representation $W$.

Let us begin with the classical case of a single set of variables. When $X = [x_1, \ldots, x_n]$, we consider the coinvariant space $R_n$, defined by

$$R_n = \mathbb{C}[X]/\langle\{\sum_{i=1}^n x_i^r | r \geq 1\}\rangle,$$

where $\langle S \rangle$ denotes the ideal generated by the set $S$. It is known [1] that $R_n$ is isomorphic to the regular representation of $S_n$. In particular, $\dim(R_n) = n!$ and $\dim(R_n^*) = 1$. There exist explicit bases of $R_n$ indexed by permutations.

Let us now move to two sets of variables. In the early nineties, Garsia and Haiman introduced an analogue of $R_n$ for $X = \begin{bmatrix} x_1 & \cdots & x_n \\ y_1 & \cdots & y_n \end{bmatrix}$, and called it the diagonal coinvariant space [16]:

$$DR_{2,n} = \mathbb{C}[X]/\langle\{\sum_{i=1}^n x_i^r y_i^t | r + t \geq 1\}\rangle.$$

About ten years later, using advanced algebraic geometry [15], Haiman settled several conjectures of [16] concerning the space, proving in particular that

$$\dim(DR_{2,n}) = (n + 1)^{n-1} \quad \text{and} \quad \dim(DR_{2,n}^*) = \frac{1}{n+1} \binom{2n}{n}. \quad (2)$$

He also studied an extension of $DR_{2,n}$ involving an integer parameter $m$ and the ideal $A$ generated by alternants [16]:

$$A = \langle\{f(x)|\sigma(f(X)) = (-1)^{\text{inv}(\sigma)}f(X), \forall \sigma \in S_n\}\rangle.$$
The number of intervals in the $m$-Tamari lattices

The $m$-extension of $\text{DR}_{2,n}$ is defined as

$$\text{DR}_{2,n}^m = \mathcal{A}^{m-1}/\langle \{ \sum_{i=1}^{n} x_i^r y_i^t | r, t \geq 1 \} \rangle \mathcal{A}^{m-1},$$

where the case $m = 1$ (with $\mathcal{A}^0 = \mathbb{C}[X]$) corresponds to $\text{DR}_{2,n}$. Aiman [15] generalized (2) by proving

$$\dim(\text{DR}_{2,n}^m) = (mn + 1)^{n-1} \text{ and } \dim(\text{DR}_{2,n}^m) = \frac{1}{mn + 1} \left( \frac{(m+1)n}{n} \right).$$

Both dimensions have simple combinatorial interpretations: we recognize the latter as the number of $m$-ballot paths of size $n$, and the former as the number of $m$ parking functions of size $n$ (these functions can be described as $m$-ballot paths of size $n$ in which non-negative steps are labelled from 1 to $n$ in such a way that labels increase along each run of non-negative steps; see e.g. [28]). However, it is still an open problem to find bases of $\text{DR}_{2,n}^m$ or $\text{DR}_{2,n}^m$ indexed by these simple combinatorial objects.

For $\ell \geq 3$, the spaces $\text{DR}_{\ell,n}$ and their generalization $\text{DR}_{\ell,n}^m$ can be defined similarly. Aiman explored the dimension of $\text{DR}_{\ell,n}$ and $\text{DR}_{\ell,n}^m$. For $\ell = 3$, we observed in [16] that, for small values of $n$,

$$\dim(\text{DR}_{3,n}) = 2^n (n+1)^{n-2} \text{ and } \dim(\text{DR}_{3,n}^\ell) = \frac{2}{n(n+1)} \left( \frac{4n+1}{n-1} \right).$$

Following discussions with Aiman, Bergeron came up with conjectures that directly imply the following generalization (since $\text{DR}_{3,n}^\ell$ coincides with $\text{DR}_{3,n}$):

$$\dim(\text{DR}_{3,n}^m) = (m+1)^n (mn+1)^{n-2} \text{ and } \dim(\text{DR}_{3,n}^\ell) = \frac{m+1}{n(n+1)} \left( \frac{(m+1)^2 n + m}{n-1} \right).$$

Both conjectures are still open.

A much simpler problem consists in asking whether these dimensions again have a simple combinatorial interpretation. Bergeron, starting from the sequence $\frac{2}{n(n+1)} \left( \frac{4n+1}{n-1} \right)$, found in Sloane’s Encyclopedia that $n$ is number counts, among others, certain ballot-related objects, namely intervals in the Tamari lattice [11]. From this observation, we were led to introduce the $m$-Tamari lattice $T_{n}^{(m)}$, and conjectured that $\frac{m+1}{n(n+1)} \left( \frac{(m+1)^2 n + m}{n-1} \right)$ is the number of intervals in $T_{n}^{(m)}$. This is the conjecture we prove in this paper. Another of its conjectures is that $\frac{(m+1)^n (mn+1)^{n-2}}{n-1}$ is the number of Tamari intervals where larger paths are “decorated” by an $m$-parking function [3]. This is proved in [5].

2. A functional equation for the generating function of intervals

The aim of this section is to describe a recursive decomposition of $m$-Tamari intervals, and to translate it into a functional equation satisfied by the associated generating function (Proposition 8). There are two main tools:

- we prove that $T_{n}^{(m)}$ can be seen as an upper ideal of the usual Tamari lattice $T_{nn}$,
- we give a simple criterion to decide whether two paths of the Tamari lattice are comparable.

2.1. An alternative description of the $m$-Tamari lattices

Our first transformation is totally armless: we apply a 45 degree rotation to 1-ballot paths to transform them into Dyck paths. A Dyck path of size $n$ consists of steps $(1,1)$ (up steps) and steps $(1,-1)$ (down steps), starts at $(0,0)$, ends at $(0,2n)$ and never goes below the $x$-axis.

We now introduce some terminology, and use it to represent the description of the (usual) Tamari lattice $T_n$. Given a Dyck path $P$, and an up step $u$ of $P$, the strictest portion of $P$ at starts at $u$ and forms a (translated) Dyck path is called the excursion of $u$ in $P$. We say that $u$ and $t$ are final step of its excursion match each other. Finally, we say that $t$ at $u$ as $mnk i$ if it is the $i$th up step of $P$. 
Given two Dyck paths \( P \) and \( Q \) of size \( n \), \( Q \) covers \( P \) in the Tamari lattice \( T_n \) if and only if there exists in \( P \) a down step \( d \), followed by an up step \( u \), such that \( Q \) is obtained from \( P \) by swapping \( d \) and \( S \), where \( S \) is the excursion of \( u \) in \( P \). This description implies the following property [4, Cor. 2.2].

**Property 3.** If \( P \preceq Q \) in \( T_n \) then \( P \) is below \( Q \). That is, for \( i \in [0..2n] \), the ordinate of the vertex of \( P \) lying at abscissa \( i \) is at most the ordinate of the vertex of \( Q \) lying at abscissa \( i \).

Consider now an \( m \)-ballot path of size \( n \), and replace each north step by a sequence of \( m \) north steps. \( T \) gives a \( 1 \)-ballot path of size \( mn \), and \( T \) us, after a rotation, a Dyck path. In \( T \) is pat, for each \( i \in [0..n-1] \), the up steps of ranks \( mi + 1, \ldots, m(i+1) \) are consecutive. We call \( T \) a Dyck path \( s \) satisfying \( T \) is property \( m \)-Dyck paths. Clearly, \( m \)-Dyck path \( s \) of size \( mn \) are in one-to-one correspondence with \( m \)-ballot paths of size \( n \). Consider now the relation \( \prec \) of Definition 2: once reformulated in terms of Dyck path \( s \), it becomes a covering relation in the usual Tamari lattice (Figure 4). Conversely, it is easy to check that if \( P \) is an \( m \)-Dyck path and \( Q \) covers \( P \) in the usual Tamari lattice, then \( Q \) is also an \( m \)-Dyck path, and there is an \( m \)-ballot path \( s \) corresponding to \( P \) and \( Q \) are related by \( \prec \). We have proved the following result.

![Figure 4. The relation \( \prec \) of Figure 2 reformulated in terms of \( m \)-Dyck paths.](image)

**Proposition 4.** The transitive closure of the relation \( \prec \) defined in Definition 2 is a lattice on \( m \)-ballot paths of size \( n \). This lattice is isomorphic to the sublattice of the Tamari lattice \( T_{mn} \) consisting of the elements that are larger than or equal to the Dyck path \( u^md^m \ldots u^md^m \). The relation \( \prec \) is the covering relation of this lattice.

**Notation.** From now on, we only consider Dyck paths \( s \). We denote by \( T \) the set of Dyck path \( s \), and by \( T_n \) the Tamari lattice of Dyck path \( s \) of length \( n \). By \( T^{(m)} \) we mean the set of \( m \)-Dyck path \( s \), and by \( T^{(m)}_n \) the Tamari lattice of \( m \)-Dyck path \( s \) of size \( mn \). \( T \) is lattice is a sublattice of \( T_{mn} \). Note that \( T^{(1)} = T \) and \( T^{(1)}_n = T_n \).

### 2.2 Distance functions

Let \( P \) be a Dyck path of size \( n \). For an up step \( u \) of \( P \), we denote by \( \ell_P(u) \) the size of the excursion of \( u \) in \( P \). The function \( D_P : [1..n] \rightarrow [1..n] \) defined by \( D_P(i) = \ell(u_i) \) is the \( i \)th up step of \( P \), is called the distance function of \( P \). It will sometimes be convenient to see \( D_P \) as a vector \( (\ell(u_1), \ldots, \ell(u_n)) \) with \( n \) components. In particular, we will compare distance functions component-wise. The main result of this section is a description of the Tamari order in terms of distance functions. \( T \) is simple, a characterizing seems to be new.

**Proposition 5.** Let \( P \) and \( Q \) be two walks in the Tamari lattice \( T_n \). Then \( P \preceq Q \) if and only if \( D_P \preceq D_Q \).

In order to prove this, we first describe the relation between the distance functions of two paths \( s \) related by a covering relation.

**Lemma 6.** Let \( P \) be a Dyck path, and \( d \) a down step of \( P \) followed by an up step \( u \). Let \( S \) be the excursion of \( u \) in \( P \), and let \( Q \) be the path obtained from \( P \) by swapping \( d \) and \( S \). Let \( u' \) be the up step matched with \( d \) in \( P \), and let the rank of \( u' \) in \( P \). Then \( D_Q(i) = D_P(i) \) for each \( i \neq i_0 \) and \( D_Q(i_0) = D_P(i_0) + \ell_P(u) \).
T is lemma is easily proved using Figure 5. It already implies that \( D_P \leq D_Q \) if \( P \leq Q \). The next lemma establishes the reverse implication, thus concluding the proof of Proposition 5.

**Lemma 7.** Let \( P \) and \( Q \) be two Dyck paths of size \( n \) such that \( D_P \leq D_Q \). Then \( P \leq Q \) in the Tamari lattice \( T_n \).

**Proof.** Let us first prove, by induction on the size, that \( P \) is below \( Q \) (in the sense of Property 3). This is clearly true if \( n = 0 \), so we assume \( n > 0 \).

Let \( u \) be the first up step (in \( P \) and \( Q \)). Note that \( \ell_P(u) = D_P(1) \leq D_Q(1) = \ell_Q(u) \). Let \( P' \) (resp. \( Q' \)) be the path obtained from \( P \) (resp. \( Q \)) by contracting \( u \) and its down step matched with \( u \). Observe that \( D_{P'} \leq D_{Q'} \), and hence by induction hypothesis, \( P' \) is below \( Q' \). Let us consider momentarily Dyck paths as functions, and write \( P(i) = j \) if \( u \) is the vertex of \( P \) lying at abscissa \( i \) as ordinate \( j \). Note that \( P(i) = Q'(i - 1) + 1 \) for \( 1 \leq i < 2\ell_P(u) \), and \( P(i) = P'(i - 2) \) for \( 2\ell_P(u) \leq i \leq 2n \). Similarly \( Q(i) = Q'(i - 1) + 1 \) for \( 1 \leq i < 2\ell_Q(u) \), and \( Q(i) = Q'(i - 2) \) for \( 2\ell_Q(u) \leq i \leq 2n \). Since \( \ell_P(u) \leq \ell_Q(u) \) and \( P'(i) \leq Q'(i) \) for \( 0 \leq i \leq 2n - 2 \), one easily checks that \( P(i) \leq Q(i) \) for \( 0 \leq i \leq 2n \), so \( P \) is below \( Q \).

In order to prove that \( P \leq Q \), we proceed by induction on \( \|D_P - D_Q\| \), where \( \|x_1, \ldots, x_n\| = |x_1| + \cdots + |x_n| \). If \( D_P = D_Q \), then \( P = Q \), because \( P \) is above \( Q \) and \( Q \) is below \( P \). So let us assume that \( D_P \neq D_Q \). Let \( i \) be minimal such that \( D_P(i) < D_Q(i) \). We claim that \( P \) and \( Q \) coincide at least until the up step of rank \( i \). Indeed, since \( P \) is below \( Q \), the path \( P \) and \( Q \) coincide up to some abscissa, and then we find a down step \( \delta \) in \( P \) but an up step in \( Q \). Let \( j \) be the rank of the up step \( \delta \), and we denote \( u \) by \( u \). Let \( d \) be the down step matched with \( u \) in \( P \) (Figure 6). Since \( D_P(i) < D_Q(i) \), \( P \) is not a step of \( Q \). The step of \( Q \) located at the same abscissa as \( d \) ends strictly below \( u \), contradicting the minimality of \( i \). Figure 6. Why \( s \) cannot be descending.

Let us prove by contradiction that \( s \) is an up step. Assume \( s \) is down. Then \( s \) is matched with an up step \( u' \) of rank \( j < i \) (Figure 6). Hence \( u' \) belongs to \( Q \) and as rank \( j \) in \( Q \). Since \( s \) cannot belong to \( Q \), it implies that \( D_P(j) < D_Q(j) \), which contradicts the minimality of \( i \).
Hence $s$ is an up step of $P$ (Figure 7). Let $S$ be the excursion of $s$ in $P$. Since $\ell_Q(u) > \ell_P(u)$ and since $Q$ is above $P$, we ave $\ell_Q(u) \geq \ell_P(u) + \ell_P(s)$, i.e., $D_Q(i) \geq D_P(i) + \ell_P(s)$. Let $P'$ be the pat obtained from $P$ by swapping $s$ and $S$. Then $P'$ covers $P$ in the Tamari lattice. By Lemma 6, $D_P = D_{P'}$ except at index $i$ (the rank of $u$), where $D_{P'}(i) = D_P(i) + \ell_P(s)$. Since $D_P(i) + \ell_P(s) \leq D_Q(i)$, we ave $D_P \leq D_Q$. But $\|D_P - D_Q\| = \|D_{P'} - D_Q\| - \ell_P(s)$ and by the induction hypothesis, $P' \leq Q$ in the Tamari lattice. Hence $P < P'$, and the lemma is proved.

2.3. Recursive decomposition of intervals and functional equation

A contact of a Dyck path $P$ is a vertex of $P$ lying on the $x$-axis. It is initial if it is $(0, 0)$. A contact of a Tamari interval $[P, Q]$ is a contact of the lower path $P$. The recursive decomposition of intervals at which we use makes the number of contacts crucial, and we say that $t$ is parameter is catalytic. We also consider another, non-catalytic parameter, which we find to be equidistributed with non-initial contacts (even more, the joint distribution of these two parameters is symmetric).

Given an $m$-Dyck path $Q$, the length of the initial run of up steps is of the form $mk$; the integer $k$ is called the initial rise of $Q$. The initial rise of an interval $[P, Q]$ is the initial rise of the upper path $Q$. The aim of this subsection is to establish the following functional equation.

**Proposition 8.** For $m \geq 1$, let $F(x) \equiv F^{(m)}(t; x)$ be the generating function of $m$ Tamari intervals, where $t$ counts the size (divided by $m$) and $x$ the number of contacts. Then

$$F(x) = x + xt \left( F(x) \cdot \Delta \right)^{(m)} (F(x)),$$

where $\Delta$ is the following divided difference operator

$$\Delta S(x) = \frac{S(x) - S(1)}{x - 1},$$

and the power $m$ means that the operator $G(x) \mapsto F(x) \cdot \Delta G(x)$ is applied $m$ times to $F(x)$.

More generally, if $F(x, y) \equiv F^{(m)}(t; x, y)$ keeps track in addition of the initial rise (via the variable $y$), we have the following functional equation:

$$F(x, y) = x + xyt \left( F(x, 1) \cdot \Delta \right)^{(m)} (F(x, y)).$$

(3)

**Examples**

1. When $m = 1$, the above equation reads

$$F(x, y) = x + xyt \left( F(x, 1) \cdot \Delta (F(x, y)) = x + xyt F(x, 1) \frac{F(x, y) - F(1, y)}{x - 1}. $$

When $y = 1$, we obtain, in the terminology of [6], a quadratic equation with one catalytic variable:

$$F(x) = x + xt F(x) \frac{F(x) - F(1)}{x - 1}.$$

![Figure 7. General form of $P$ and $Q$.](image-url)
2. When $m = 2$,

$$F(x, y) = x + xyt F(x, 1) \cdot \Delta(F(x, 1) \cdot \Delta(F(x, y)))$$

$$= x + xyt F(x, 1) \cdot \Delta \left( F(x, 1) \frac{F(x, y) - F(1, y)}{x - 1} \right)$$

$$= x + \frac{xt}{x - 1} F(x, 1) \left( F(x, 1) \frac{F(x, y) - F(1, y)}{x - 1} - F(1) F'(1) \right),$$

where derivative is taken with respect to the variable $x$. When $y = 1$, we obtain a cubic equation with one catalytic variable:

$$F(x) = x + \frac{xt}{x - 1} F(x) \left( F(x) \frac{F(x) - F(1)}{x - 1} - F(1) F'(1) \right).$$

The solution of (3) will be the topic of the next section. For the moment we focus on the proof of $t$ is equation.

We say $t$ at a vertex $q$ lies to the right of a vertex $p$ if the abscissa of $q$ is greater than or equal to the abscissa of $p$. A $k$-pointed Dyck path is a tuple $(P; p_1, \ldots, p_k)$ where $P$ is a Dyck path and $p_1, \ldots, p_k$ are contacts of $P$ such that $p_{i+1}$ lies to the right of $p_i$, for $1 \leq i < k$ (note $t$ at some $p_i$'s may coincide). Given an $m$-Dyck path $P$ of positive size, let $u_1, \ldots, u_m$ be the initial (consecutive) up steps of $P$, and let $d_1, \ldots, d_m$ be the down steps starting with $u_1, \ldots, u_m$, respectively. The $m$-reduction of $P$ is the $m$-pointed Dyck path $(P'; p_1, \ldots, p_m)$ where $P'$ is obtained from $P$ by contracting all the steps $u_1, \ldots, u_m, d_1, \ldots, d_m$, and $p_1, \ldots, p_m$ are the vertices of $P'$ resulting from the contraction of $d_1, \ldots, d_m$. It is easy to check that any Dyck path is indeed a contact of $P'$ (Figure 8).

![Figure 8. The m-reduction of an m-Dyck path (m = 2).](image)

The map $P \mapsto (P'; p_1, \ldots, p_m)$ is clearly invertible, since $m$-Dyck paths of size $mn$ are in bijection with $m$-pointed $m$-Dyck paths of size $m(n-1)$. Note that the non-initial contacts of $P$ correspond to the contacts of $P'$ at the right of $p_m$. Note also that the distance function $D_{P'}$ (seen as a vector with $m(n-1)$ components) is obtained by deleting the first $m$ components of $D_P$. Conversely, denoting by $2x$ the abscissa of $p_i$. $D_P$ is obtained by prepending to $D_{P'}$ the sequence $(x_m + m, x_{m-1} + m - 1, \ldots, x_1 + 1)$. In view of Proposition 5, it is given the following recursive characterization of intervals.

**Lemma 9.** Let $P$ and $Q$ be two $m$-Dyck paths of size $mn > 0$. Let $(P'; p_1, \ldots, p_m)$ and $(Q'; q_1, \ldots, q_m)$ be the $m$-reductions of $P$ and $Q$ respectively. Then $P \leq Q$ in $T_n^{(m)}$ if and only if $P' \leq Q'$ in $T_{n-1}^{(m)}$ and for $i \in [1..m]$, the point $q_i$ lies to the right of $p_i$.

The non-initial contacts correspond to the contacts of $P'$ located to the right of $p_m$.

Let us call $k$-pointed interval in $T^{(m)}$ a pair consisting of two $k$-pointed $m$-Dyck paths $(P; p_1, \ldots, p_k)$ and $(Q; q_1, \ldots, q_k)$ such that $P \leq Q$ and for $i \in [1..k]$, the point $q_i$ lies to the right of $p_i$. An active contact of such a pair is a contact of $P$ lying to the right of $p_k$ (if $k = 0$, all contacts are declared active). For $0 \leq k \leq m$, let us denote by $G^{(m,k)}(t; x, y) \equiv G^{(k)}(x, y)$ the generating function of $k$-pointed $m$-Tamari intervals, where $t$ counts the size (divided by $m$), $x$
the number of active contacts, and $y$ the initial rise (we drop the superscript $m$ since it will not vary). In particular, the series we are interested in is
\[ F(x, y) = G^{(0)}(x, y). \] (4)

Moreover, Lemma 9 implies
\[ F(x, y) = x + xyt G^{(m)}(x, y). \] (5)

We will prove that, for $k \geq 0$,
\[ G^{(k+1)}(x, y) = F(x, 1) \cdot \Delta G^{(k)}(x, y). \] (6)

The functional equation (3) then follows using (4) and (5).

For $k \geq 0$, let $I = [P^*, Q^*]$ be a $(k+1)$-pointed interval in $T^{(m)}$, with $P^* = (P; p_1, \ldots, p_{k+1})$ and $Q^* = (Q; q_1, \ldots, q_{k+1})$. Since $P$ is below $Q$, the contact $q_{k+1}$ of $Q$ is also a contact of $P$. By definition of pointed intervals, $q_{k+1}$ is to the right of $p_{k+1}$. Decompose $P$ as $P = P_2 P_1$ were $P_2$ is the part of $P$ to the left of $q_{k+1}$ and $P_1$ is the part of $P$ to the right of $q_{k+1}$. Decompose similarly $Q$ as $Q_1 Q_2$, were the two factors meet at $q_{k+1}$. The distance function $D_P$ (seen as a vector) is $D_{P_2}$ concatenated with $D_{P_1}$, and similarly for $D_Q$. In particular, $D_{P_2} \leq D_{Q_2}$ and $D_{P_1} \leq D_{Q_1}$. By Proposition 5, $I_r = [P_r, Q_r]$ is an interval, were $I_r := [P^*, Q^*]$, with $P^* = (P; p_1, \ldots, p_k)$ and $Q^* = (Q; q_1, \ldots, q_k)$, is a $k$-pointed interval. Its initial rise equals the initial rise of $I$. We denote by $\Phi$ the map $t \mapsto I_t$ to the pair of intervals $(I_t, I_r)$.

Conversely, take an interval $I_r = [P_r, Q_r]$ and a $k$-pointed interval $I_t = [P^*, Q^*]$, were $P^* = (P; p_1, \ldots, p_k)$ and $Q^* = (Q; q_1, \ldots, q_k)$. Let $P = P_t P_r$, $Q = Q_r Q_t$, and denote by $q_{k+1}$ the point were $Q_t$ and $Q_r$ (and $P_t$ and $P_r$) meet. $T$ is a contact of $P$ and $Q$. $T$ en the $i$ preimages of $(I_r, I_t)$ by $\Phi$ are all the intervals $I = [P^*, Q^*]$ such that $t = [P^*; p_1, \ldots, p_{k+1}]$ and $Q^* = (Q; q_1, \ldots, q_{k+1})$, were $p_{k+1}$ is any active contact of $P_t$. If $P_t$ is an active contact and $P_r$ is $j$ contacts, $t \mapsto (I_t, I_r)$ as $i$ preimages, aving respectively $j + 1, j + 1, \ldots, j + 1$ active contacts (j active contacts were $p_{k+1} = q_{k+1}$, and $j + 1$ active contacts were $p_{k+1} = p_k$). Let us write $G^{(k)}(x, y) = \sum_{i \geq 0} G_i^{(k)}(y)x^i$, so that $G_i^{(k)}(y)$ counts (by the size and the initial rise) $k$-pointed intervals with $i$ active contacts. The above discussion gives
\[
G^{(k+1)}(x, y) = F(x, 1) \sum_{i \geq 1} G_i^{(k)}(y)(1 + x + \cdots + x^{i-1})
\]
\[
= F(x, 1) \sum_{i \geq 1} G_i^{(k)}(y) \frac{x^i - 1}{x - 1}
\]
\[
= F(x, 1) \cdot \Delta G^{(k)}(x, y),
\]

as claimed in (6). The factor $F(x, 1)$ accounts for the size of $I_r$, and the term $\Delta G^{(k)}(x, y)$ for the size of $I_t$ and $p_{k+1}$. $T$ is complete the proof of Proposition 8.

### 3. Solution of the Functional Equation

In this section, we solve the functional equation of Proposition 8, and thus establish the main result of the paper. We obtain in particular an unexpected symmetry property: the series $y F^{(m)}(t; x, y)$ is symmetric in $x$ and $y$. In other words, the joint distribution of the number of non-initial contacts (of the lower pat) and the initial rise (of the upper pat) is symmetric.

For any ring $A$, we denote by $A[x]$ the ring of polynomials in $x$ with coefficients in $A$, and by $A[[x]]$ the ring of formal power series in $x$ with coefficients in $A$. $T$ is notation is extended to the case of polynomials and series in several indeterminates $x_1, x_2, \ldots$

**Theorem 10.** For $m \geq 1$, let $F^{(m)}(t; x, y)$ be the generating function of Tamari intervals, where $t$ counts the size (divided by $m$), $x$ the number of contacts of the bottom path, and $y$ the initial rise of the upper path. Let $z$, $u$ and $v$ be three indeterminates, and set
\[
t = z(1 - z)^{m^2 + 2m}, \quad x = \frac{1 + u}{(1 + uz)^{m+1}}, \quad \text{and} \quad y = \frac{1 + v}{(1 + zv)^{m+1}}.
\] (7)
Then $F^{(m)}(t; x, y)$ becomes a formal power series in $z$ with coefficients in $\mathbb{Q}[u, v]$, and this series is rational. More precisely,

$$yF^{(m)}(t; x, y) = \frac{(1 + u)(1 + zu)(1 + v)(1 + zv)}{(u - v)(1 - zuv)(1 - z)^{m+2}} \left( \frac{1 + u}{(1 + zu)^{m+1}} - \frac{1 + v}{(1 + zv)^{m+1}} \right). \quad (8)$$

In particular, $yF^{(m)}(t; x, y)$ is a symmetric series in $x$ and $y$.

**Remark.** $T$ is result was first guessed for small values of $m$. More precisely, we first guessed the values of $\frac{d^i F(1,1)}{dz^i}(1,1)$ for $0 \leq i \leq m - 1$, and then combined these conjectured values with functional equations to obtain conjectures for $F(x,1)$ and $F(x,y)$. Let us illustrate our guessing procedure on the case $m = 1$. We first consider the case $y = 1$, where the equation reads

$$F(x,1) = x + xtF(x,1) \frac{F(x,1) - F(1,1)}{x - 1}. \quad (9)$$

Our first objective is to guess the value of $F(1,1)$. Using the above equation, we can easily compute, say, the 20 first coefficients of $F(1,1)$. Using the Maple package `gfun` [24], we conjecture from the list of coefficients $t$ at $f = F(1,1)$ satisfies

$$1 - 16 t - (1 - 20 t) f - (3 t + 8 t^2) f^2 - 3 t^2 f^3 - t^3 f^4 = 0.$$

Using the package `algcurves`, we find that the above equation admits a rational parametrization, for instance

$$t = z(1 - z)^3, \quad f = F(1,1) = \frac{1 - 2z}{(1 - z)^3}.$$

T is the end of the “gues the” part. Assume the above identity holds, and replace $t$ and $F(1,1)$ in (9) by their expressions in terms of $z$. $T$ is gives an algebraic equation in $F(x,1)$, $x$ and $z$. Again, the package `algcurves` reveals that the equation, seen as an equation in $F(x,1)$ and $x$, admits a rational parametrization, for instance

$$x = \frac{1 + u}{(1 + zu)^2}, \quad F(x,1) = \frac{(1 + u)(1 - 2z - z^2 u)}{(1 + zu)(1 - z)^3}.$$

Let us finally return to the functional equation defining $F(x,y)$:

$$F(x,y) = x + yxF(x,1) \frac{F(x,y) - F(1,y)}{x - 1}.$$

In the equation, replace $t$, $x$ and $F(x,1)$ by their conjectured expressions in terms of $z$ and $u$. $T$ is given

$$\left( 1 + zu - yu \frac{(1 + u)^2}{u} \right) F(x,y) = \frac{1 + u}{1 + zu} - yu \frac{(1 + u)^2}{u} F(1,y). \quad (10)$$

We conclude by applying to the equation the kernel method (see, e.g. [2, 7, 23]): let $U \equiv U(z;y)$ be the unique formal power series in $z$ (with coefficients in $\mathbb{Q}[y]$) satisfying

$$U = zy(1 + U)^2 - zU^2.$$

Equivalently,

$$U = z \frac{1 + v}{1 - 2z - z^2 v}, \quad \text{with} \quad y = \frac{1 + v}{(1 + zu)^2}.$$

Setting $u = U$ in (10) cancels the left- and right-hand sides, and the right-hand side, giving

$$yF(1,y) = \frac{(1 + v)(1 - 2z - z^2 v)}{(1 + zv)(1 - z)^3}.$$

A conjecture for the trivariate series $F(t;x,y)$ follows, using (10). $T$ is conjectured coincides with (8). \[ \square \]

\[ ^2 \text{For a general value of } m, \text{one has to guess the series } \frac{d^i F(1,1)}{dz^i} \text{ for } 0 \leq i \leq m - 1. \text{ All of them are found to be rational functions of } z, \text{ when } t = z(1 - z)^{m^2 + 2m}. \]
Before we prove Theorem 10, let us give a closed form expression for the number of intervals in $T_n^{(m)}$.

**Corollary 11.** Let $m \geq 1$ and $n \geq 1$. The number of intervals in the Tamari lattice $T_n^{(m)}$ is

$$f_n^{(m)} = \frac{\bar{m}}{n(nm + 1)} \binom{nm^2 + m}{n - 1},$$

where we denote $\bar{m} = m + 1$. For $2 \leq i \leq n + 1$, the number of intervals in which the bottom path has $i$ contacts with the $x$ axis is

$$f_n^{(m)} = \frac{(nm^2 - im + m)!((\bar{m} - m))!}{(nm^2 - n - im + 2m)!((n - i + 1)((\bar{m} - i - 2))!} P_m(n, i),$$

where $P_m(n, i)$ is a polynomial in $n$ and $i$. In particular,

$$P_1(n, i) = 2, \quad P_2(n, i) = 6(33in - 9i^2 + 15i - 2n - 2).$$

More generally,

$$i(i - 1)P_m(n, i) = -\bar{m}!(m - 1)!(n - i + 1)\left(\frac{i\bar{m}}{m}\right)\binom{nm(m + 2) - im + 2m}{m - 1}$$

$$+ \sum_{k=1}^{m-2} kk!^2(m - k - 2)!((m - k - 1)!((i + 1)m\bar{m} + 2m + k)(n - i)(n - i + 1)\times$$

$$\binom{i\bar{m} - k - 1}{m - k - 1} \binom{im}{k} \binom{nm^2 - i\bar{m} + m + k}{m - k - 2} \binom{nm^2 - i\bar{m} + 2m}{m - k - 2}$$

$$+ m!^2\binom{im}{m - 1} i\left(\frac{nm^2 - i\bar{m} + 2m}{m}\right) - \frac{m - 1}{m}\left(\frac{nm^2 - i\bar{m} + 2m - 1}{m - 1}\right).$$

**Remarks**

1. The case $m = 1$ of (11) reads

$$f_{n, 1}^{(1)} = \frac{(i - 1)(4n - 2i + 2)!}{(3n - i + 2)!((n - i + 1)!} \binom{2i}{i}.\)$$

This result can also be obtained using Bernardi and Bonic's bijection between intervals of size $n$ in the (usual) Tamari lattice and planar 3-connected triangulations having $n + 3$ vertices [4]. Indeed, through bijection, the number of contacts in the lower path of the interval becomes the degree of the root-vertex of the triangulation, minus one [4, Def 3.2]. The above result is thus equivalent to an old result of Brown counting triangulations by the number of vertices and the degree of the root-vertex [9, Eq. (4.7)].

2. Our expression of $P_m$ is not illuminating, but we have given it to prove that $P_m$ is indeed a polynomial. If we fix $i$ rather than $m$, and $n$, then $P_m(n, i)$ seems to be a sum of two hypergeometric terms in $m$ and $n$. More precisely, it appears that

$$P_m(n, i) = \frac{m!^2i!}{(im - m)!(i - 1)!} \times$$

$$\left(\bar{m} R_i(m, n) \frac{nm^2 - (i - 2)m - 1}{\bar{m}} + Q_i(m, n) \frac{nm(m + 2) - (i - 2)m}{m}\right),$$

where $R_i$ and $Q_i$ are two polynomials in $m$ and $n$.

3. The coefficients of the trivariate series $F(t; x, y)$ do not seem to have small prime factors, even when $m = 1$.

**Proof of Theorem 10.** The functional equation of Proposition 8 defines a unique formal power series in $t$ (think of extracting inductively the coefficient of $t^n$ in $F(t; x, y)$). The coefficients
of $t$ is series are polynomials in $x$ and $y$. The parametrized expression of $F(t; x, y)$ given in Theorem 10 also defines $F(t; x, y)$ uniquely as a power series in $t$, because (7) defines $z$, $u$, and $v$ uniquely as formal power series in $t$ (with coefficients in $Q$, $Q[x]$ and $Q[y]$ respectively). Thus it suffices to prove that the series $F(t; x, y)$ of Theorem 10 satisfies the equation of Proposition 8.

Let $G(t; x, y) \equiv G(x, y) \in Q[x, y][[t]]$, and perform the change of variables (7). Then $G(t; x, y) = H(z; u, v)$, where

$$H(z; u, v) \equiv H(u, v) = G \left( z(1 - z)^{m^2 + 2m}, \frac{1 + u}{(1 + zu)^{m + 1}}, \frac{1 + v}{(1 + zv)^{m + 1}} \right).$$

Moreover, if $F(x, y)$ is given by (8), then

$$F(x, 1) = \frac{(1 + u)(1 + zu)}{u(1 - z)^{m + 2}} \left( \frac{1 + u}{(1 + zu)^{m + 1}} - 1 \right),$$

and

$$F(x, 1) \Delta G(x, y) = \frac{(1 + u)(1 + zu)}{(1 - z)^{m + 2}} H(u, v) - H(0, v).$$

Let us define an operator $\Lambda$ as follows: for any series $H(z; u, v) \in Q[u, v][[z]]$,

$$\Lambda H(z; u, v) := (1 + u)(1 + zu) H(z; u, v) - H(z; 0, v). \quad (13)$$

Then the series $\Delta F(t; x, y)$ of Theorem 10 satisfies the equation of Proposition 8 if and only if the series $H(u, v)$ obtained by performing the change of variables (7) in $y(1 - z)^{m^2 + 2} F(x, y)$, at $t$, is

$$H(u, v) = \frac{(1 + u)(1 + zu)(1 + v)(1 + zv)}{(u - v)(1 - zuv)} \left( \frac{1 + u}{(1 + zu)^{m + 1}} - 1 \right), \quad (14)$$

satisfies

$$z\Lambda(m) H(u, v) = \frac{(1 + zu)^{m + 1}(1 + zv)^{m + 1}}{(1 + u)(1 + v)} H(u, v) - (1 - z)^{m + 2}. \quad (15)$$

Hence we simply have to prove an identity on rational functions. Observe that both $H(u, v)$ and the conjectured expression of $\Lambda(m) H(u, v)$ are symmetric in $u$ and $v$. More generally, computing with the help of MAPLE the rational functions $\Lambda(k) H(u, v)$ for a few values of $m$ and $k$ suggests that these fractions are always symmetric in $u$ and $v$. It is observation raises the following question: Given a symmetric function $H(u, v)$, when is $\Lambda H(u, v)$ also symmetric? This leads to the following lemma, which will reduce the proof of (15) to the case $v = 0$.

**Lemma 12.** Let $H(z; u, v) = H(u, v)$ be a series of $Q[u, v][[z]]$, symmetric in $u$ and $v$. Let $\Lambda$ be the operator defined by (13), and denote $H_1(u, v) := \Lambda H(u, v)$. Then $H_1(u, v)$ is symmetric in $u$ and $v$ if and only if $H$ satisfies

$$H(u, v) = \frac{u(1 + v)(1 + zv)H(0, v) - v(1 + u)(1 + zu)H(0, v)}{(u - v)(1 - zuv)}. \quad (16)$$

If this holds, then $H_1(u, v)$ also satisfies (16) (with $H$ replaced by $H_1$). By induction, the same holds for $H_k(u, v) := \Lambda(k) H_1(u, v)$.

The proof is a straightforward calculation.

Note that a series $H$ satisfying (16) is characterized by the value of $H(0, 0)$. The series $H(u, v)$ given by (14) satisfies (16), with

$$H(u, 0) = \frac{(1 + u)(1 + zu)}{u} \left( \frac{1 + u}{(1 + zu)^{m + 1}} - 1 \right) = \Lambda \left( \frac{1 + u}{(1 + zu)^{m + 1}} \right).$$

Moreover, one easily checks that the right-hand side of (15) also satisfies (16), as expected from Lemma 12. Thus it suffices to prove the case $v = 0$ of (15), namely

$$z\Lambda(m + 1) \left( \frac{1 + u}{(1 + zu)^{m + 1}} \right) = \frac{(1 + u)(1 + zu)}{u} \left( \frac{1 - (1 + zu)^{m + 1}}{1 + u} \right) - (1 - z)^{m + 2}. \quad (17)$$

This will be a simple consequence of the following lemma.
Lemma 13. Let $\Lambda$ be the operator defined by (13). For $m \geq 1$,
$$\Lambda^{(m)} \left( \frac{1}{1 + zu} \right) = (1 - z)^m - (1 + zu)^m.$$

Proof. We will actually prove a more general identity. Let $1 \leq k \leq m$, and denote $w = 1 + zu$. Then
$$\Lambda^{(k)} \left( \frac{1}{1 + zu} \right) = (1 - z)^k - \sum_{i=k}^{m-1} \sum_{j=1}^{k} \binom{k}{j} \binom{i-j+1}{k-j} \frac{(-1)^{k+j} z^{k-j+1}}{w^{m-i-1}} \left( \frac{1}{w^{i-j}} \right).$$

The case $k = m$ is the identity of Lemma 13. In order to prove (18), we need an expression of $\Lambda(w^p)$, for all $p \in \mathbb{Z}$. Using the definition (13) of $\Lambda$, one obtains, for $p \geq 1$,
$$\Lambda \left( \frac{1}{w^p} \right) = \frac{1 - z}{w^{p-1}} - z \sum_{a=0}^{p-2} \frac{1}{w^a} - w,$$
$$\Lambda(1) = 0,$$
$$\Lambda(w^p) = (z-1)w + z \sum_{a=2}^{p} w^a + w^{p+1}. \tag{19}$$

We now prove (18), by induction on $k \geq 1$. For $k = 1$, (18) coincides with the expression of $\Lambda(1/w^p)$ given above (with $p$ replaced by $m$). Now let $1 \leq k < m$. Apply $\Lambda$ to (18), use (19) to express the terms $\Lambda(w^p)$ at the appear, and check that the coefficient of $w^a z^b$ is $w$ as it is expected to be, for all values of $a$ and $b$. The details are a bit tedious, but elementary. One needs to apply a few times the following identity:
$$\sum_{r=a}^{r_2} \left( \binom{r-a}{b} \right) = \frac{(r_2 + 1 - a - b)}{b+1} \binom{r_2 + 1 - a}{b} - \frac{(r_1 - a - b)}{b+1} \binom{r_1 - a}{b}.$$ 

We give in the appendix a constructive proof of Lemma 13, which does not require to guess the more general identity (18). It is also possible to derive (18) combinatorially from (19) using one-dimensional lattice paths (in the setting, (19) describes $w$ at steps are allowed if one starts at position $p$, for any $p \in \mathbb{Z}$).

Let us now return to the proof of (17). We write
$$\frac{1 + u}{(1 + uz)^m + 1} = \frac{1}{1 + uz} + \frac{z - 1}{(1 + uz)^{m+1}}.$$ 

Thus
$$z \Lambda^{(m)} \left( \frac{1 + u}{1 + uz} \right) = \Lambda \left( \Lambda^{(m)} \left( \frac{1}{1 + uz} \right) \right) + (z-1) \Lambda^{(m+1)} \left( \frac{1}{1 + uz} \right) = \Lambda \left( (1 - z)^m - (1 + uz)^m \right) + (z-1) \left( (1 - z)^{m+1} - (1 + uz)^{m+1} \right)$$ 

by Lemma 13. Eq. (17) follows, and Theorem 10 is proved.

Proof of Corollary 11. Let us first determine the coefficient of $F(t; 1, 1)$. By letting $u$ and $v$ tend to 0 in the expression of $yF(t; x, y)$, we obtain
$$F(t; 1, 1) = \frac{1}{(1 - z)^{m+2}}.$$ 

were $t = z(1 - z)^{m^2 + 2m}$. The Lagrange inversion formula gives
$$[t^n]F(t; 1, 1) = \frac{1}{n} \left[ t^{n-1} \right] \frac{1 - (m+1)^2 t}{(1 - t)^{nm(m+2)+m+3}}.$$
and the expression of $f_n^{(m)}$ follows after an elementary coefficient extraction. We now wish to express the coefficient of $t^p x^i$ in

$$F(t; x, 1) = \frac{(1 + u)(1 + zu)}{u(1 - z)^{m+2}} \left( \frac{1 + u}{(1 + zu)^{m+1}} - 1 \right).$$

We will expand this series, first in $x$, then in $t$, applying the Lagrange inversion formula first to $u$, then to $z$. We first expand $(1 - z)^{m+2} F(t; x, 1)$ in partial fractions of $u$:

$$(1 - z)^{m+2} F(t; x, 1) = -z \chi_{m > 1} - (1 + zu) - \sum_{k=1}^{m-2} \frac{z}{k} \frac{1 - z^2}{z(1 + uz)^{m-1}} - \frac{(1 - z)^2}{z(1 + uz)^m}.$$

By the Lagrange inversion formula, applied to $u$, we have, for $i \geq 1$ and $p \geq -m$,

$$[x^i](1 + zu)^p = \frac{p}{i} \binom{\tilde{m} + p - 1}{i - 1} z^i (1 - z)^{im + p},$$

where $\tilde{m} = m + 1$. Hence, for $i \geq 1$,

$$i[x^i] F(t; x, 1) = -\binom{\tilde{m}}{i} \sum_{k=1}^{m-2} \binom{\tilde{m} - k - 1}{i} \frac{1}{(1 - z)^{i+1}(1 - z)^{(i+1)m-k-2}}$$

$$- (m - 1) \binom{\tilde{m} - m - 1}{i-1} z^{i-1}(1 + z)(1 - z)^{(i-2)m} + m \binom{\tilde{m}}{i} z^{i-1}(1 - z)^{(i-2)m}. $$

We rewrite the above line as

$$\binom{\tilde{m} - m}{i} \frac{i}{\tilde{m} - m} z^{i-1}(1 - z)^{(i-2)m} - (m - 1) z^{i-1}(1 - z)^{(i-2)m}.$$

Recall that $z = \frac{t}{1 - z}^{m+2}$. Hence, for $i \geq 1$,

$$i[x^i t^n] F(t; x, 1) = -\binom{\tilde{m}}{i} \binom{\tilde{m} + m}{i} \frac{1}{(1 - z)^{\tilde{m}(im + 1)}}$$

$$+ \sum_{k=1}^{m-2} \binom{\tilde{m} - k - 1}{i-1} \frac{1}{(1 - z)^{i+1}(1 - z)^{(i+1)m+2m+k}}$$

$$+ \binom{\tilde{m} - m}{i-1} \frac{i}{\tilde{m} - m} \sum_{k=1}^{m-2} \binom{\tilde{m} - m + 1}{i} \frac{1}{(1 - z)^{im + 2m + k}}.$$

By the Lagrange inversion formula, applied to $z$, we have, for $p \geq 1$ and $n \geq 1$,

$$[t^n] \frac{1}{(1 - z)^p} = \frac{p}{n} \binom{n \tilde{m}^2 + p - 1}{n - 1}.$$

The formula actually holds for $n = 0$ if we write it as

$$[t^n] \frac{1}{(1 - z)^p} = \frac{p (n \tilde{m}^2 + p - 1)!}{n! (n \tilde{m}^2 - n + p)!},$$

and actually for $n < 0$ as well with the convention $\binom{a}{n} = 0$ if $n < 0$. With this convention, we have, for $1 \leq i \leq n + 1$,

$$i[x^i t^n] F(t; x, 1) = -\frac{\tilde{m}(im + 1)}{n - i} \binom{\tilde{m}}{i} \frac{1}{n - i - 1} (n \tilde{m}^2 - i \tilde{m} + m + 1)$$

$$+ \sum_{k=1}^{m-2} \frac{(i + 1)m \tilde{m} + 2m + k}{n - i - 1} \binom{\tilde{m} - k - 1}{i - 1} \frac{(n \tilde{m}^2 - i \tilde{m} + m + k)}{n - i - 2}$$

$$+ m \binom{\tilde{m} - m}{i - 1} \frac{i}{n - i + 1} \frac{(n \tilde{m}^2 - i \tilde{m} + 2m)}{n - i} - (m - 1) \frac{\tilde{m}}{n - i} \frac{2 - n \tilde{m}^2 - i \tilde{m} + 2m - 1}{n - i - 1}.$$

T is given the expression (11) of \( f_{n,i}^{(m)} \) with \( P_m(n, i) \) given by (12). Clearly, \( i(i - 1)P_m(n, i) \) is a polynomial in \( n \) and \( i \), but we still have to prove that it is divisible by \( i(i - 1) \).

For \( m \geq 1 \) and \( 1 \leq k \leq m - 2 \), the polynomials \( \binom{m}{i} \) are divisible by \( i \). The next-to-last term of (12) contains an explicit factor \( i \). The last term vanishes if \( m = 1 \), and otherwise contains a factor \( \binom{m - 1}{i} \), which is a multiple of \( i \). Hence each term of (12) is divisible by \( i \).

Finally, the right-hand side of (12) is easily evaluated to be 0 when \( i = 1 \), using the sum function of Maple.

4. Final Comments

Bijective proofs? Given the simplicity of the numbers (1), it is natural to ask about a bijective enumeration of \( m \)-Tamari intervals. A related question would be to extend the bijection of [4] (which transforms 1-Tamari intervals into triangulations) into a bijection between \( m \)-Tamari intervals and certain maps (or related structures, like balanced trees or mobiles [25, 8]). Counting these structures in a bijective way (as is done in [22] for triangulations) would then provide a bijective proof of (1).

Symmetry. The fact that the joint distribution of the number of non-initial contacts of the lower part and the initial rise of the upper part is symmetric remains a combinatorial mystery to us, even when \( m = 1 \). What is easy to see is that the joint distribution of the number of non-initial contacts of the lower part and the final descent of the upper part is symmetric. Indeed, there exists a simple involution on Dyck paths such that at reverses of Tamari order and exchanges two parameters: If we consider Dyck paths as postorder encodings of binary trees, it is involution amounts to a simple reflection of trees. Via the bijection of [4], these two parameters correspond to the degrees of two vertices of the root-face of the triangulation [4, Def. 3.2], so that symmetry is also clear in this setting.

A \( q \)-analogue of the functional equation. As described in the introduction, the numbers \( f_{n,i}^{(m)} \) are conjectured to give the dimension of certain polynomial rings \( DR_{3,m}^\infty \). These rings are tri-graded (with respect to the sets of variables \( \{x_i\}, \{y_i\} \), and \( \{z_i\} \)), and it is conjectured [3] that at the dimension of the homogeneous component in the \( x_i \)'s of degree \( k \) is the number of intervals \([P, Q]\) in \( T_n^{(m)} \) such that the longest chain from \( P \) to \( Q \) in the Tamari order, as length \( k \). One can recycle the recursive description of intervals described in Section 2.3 to generalize the functional equation of Proposition 8, taking into account (with a new variable \( q \)) that is distance. Eq. (3) remains valid, upon defining the operator \( \Delta \) by

\[
\Delta S(x) = \frac{S(qx) - S(1)}{qx - 1}.
\]

The coefficient of \( t^n \) in the series \( F(t, q; x, y) \) does not seem to factor, even when \( x = y = 1 \). The coefficients of the bivariate series \( F(t, q; 1, 1) \) are large prime factors.

More on \( m \)-Tamari lattices? We do not know of any simple description of the \( m \)-Tamari lattice in terms of rotations in \( m + 1 \)-ary trees (which are equinumerous with \( m \)-Dyck paths). A rotation for ternary trees is defined in [20], but does not give a lattice. More generally, it may be worth exploring analogues for the \( m \)-Tamari lattices of the numerous questions that have been studied for the usual Tamari lattice. To mention only one, what is the diameter of the \( m \)-Tamari lattice, at is, the maximal distance between two \( m \)-Dyck paths in the Tamari diagram? When \( m = 1 \), it is known to be \( 2n - 6 \) for a large enough, but the proof is as complicated as the formula is simple [12, 26].

Acknowledgements. We are grateful to François Bergeron for advertising his lectures on conjectural interpretation of the numbers (1) in terms of Tamari intervals. We also thank Gwendal Collet and Gilles Schaeffer for interesting discussions on Tamari.
Appendix. A constructive approach to Lemma 13. In order to prove Lemma 13, we add to prove the more general identity (18). It is identity was first guessed by expanding \( \Lambda(k)(1/w^m) \) in \( w \) and \( z \), for several values of \( k \) and \( m \). Fortunately, the coefficients in \( t \) is expansion turned out to be simple products of binomial coefficients.
When to these coefficients are not been so simple? A constructive approach goes as follows. Introduce the following two formal power series in $t$ and $s$, with coefficients in $Q[w, 1/w, z]$:

$$P(t; s) = \sum_{m \geq 1} t^k s^{m-1} \Lambda(k)(w^m) \quad \text{and} \quad N(t; s) = \sum_{m \geq 0, k \geq 0} t^k s^m \Lambda(k) \left( \frac{1}{w^m} \right),$$

where we still denote $w = 1 + zu$. Observe that

$$P(t; 0) = \sum_{k \geq 0} t^k \Lambda(k)(w).$$

We want to compute the coefficient of $t^m s^m$ of $N(t; s)$, since $t$ is coefficient is $\Lambda^{(m)}(1/w^m)$.

Eqs. (19) yield functional equations for the series $P$ and $N$. For $P(t; s)$ first,

$$P(t; s) = \sum_{m \geq 1} s^{m-1} w^m + t \sum_{m \geq 1, k \geq 1} t^{k-1} s^{m-1} \Lambda(k-1) \left( (z-1)w + z \sum_{a=2}^{m} w^a + w^{m+1} \right)$$

$$= \frac{w}{1-sw} + \frac{t(z-1)}{1-s} P(t; 0) + \frac{tz}{1-s} (P(t; s) - P(t; 0)) + \frac{tP(t; s) - P(t; 0)}{s}.$$

Equivalently,

$$\left(1 - \frac{tz}{1-s} - \frac{t}{s}\right) P(t; s) = \frac{w}{1-sw} - \frac{tP(t; 0)}{s(1-s)}. \quad (20)$$

Now for $N(t; s)$, we have

$$N(t; s) = \sum_{m \geq 0} s^m w^m + t \sum_{m \geq 1, k \geq 1} t^{k-1} s^m \Lambda(k-1) \left( \frac{1-z}{w^{m-1}} - z \sum_{a=0}^{m-2} \frac{1}{w^a} - w \right)$$

$$= \frac{1}{1-s/w} + ts(1-z)N(t; s) - \frac{tzs^2}{1-s} N(t; s) - \frac{ts}{1-s} P(t; 0).$$

Equivalently,

$$\left(1 - ts + \frac{tzs}{1-s}\right) N(t; s) = \frac{1}{1-s/w} - \frac{ts}{1-s} P(t; 0). \quad (21)$$

Equation (20) can be solved using the kernel method [see e.g. [2, 7, 23]]: let $S \equiv S(t, z)$ be the unique formal power series in $t$, with coefficients in $Q[z]$, having constant term 0 and satisfying

$$1 - \frac{tz}{1-s} - \frac{t}{S} = 0.$$

That is,

$$S = \frac{1+t-tz-\sqrt{1-2t(1+z)+t^2(1-z)^2}}{2}. \quad (22)$$

Then setting $s = S$ cancels the left- and side of (20), giving

$$P(t; 0) = \frac{wS(1-S)}{t(1-wS)}.$$

Combined with (21), this yields an explicit expression of $N(t; s)$:

$$N(t; s) = \frac{1}{1-ts+\frac{tzs}{1-s}} \left( \frac{1}{1-s/w} - \frac{wsS(1-S)}{(1-s)(1-wS)} \right).$$

We want to extract from this series the coefficient of $t^m s^m$, and obtain the simple expression $(1-z)^m - w^m$ predicted by Lemma 13. Clearly, the first part of the above expression of $N(t; s)$
(with non-positive powers of $w$) contributes $(1 - z)^m$, as expected. For $i \geq 1$, the coefficient of $w^i$ in the second part of $N(t; s)$ is

$$R_i := -\frac{sS^i(1 - S)}{(1 - s)(1 - ts + \frac{tzs}{1 - s})}.\]$$

Recall that $S$, given by (22), depends on $t$ and $z$, but not on $s$. Since $S = t + O(t^2)$, the coefficient of $t^m s^m$ in $R_i$ is zero for $i > m$. When $i = m$, it is easily seen to be $-1$, as expected. In order to prove that the coefficient of $t^m s^m$ in $R_i$ is zero when $0 < i < m$, we first perform a partial fraction expansion of $R_i$ in $s$, using

$$(1 - s) \left( 1 - ts + \frac{tzs}{1 - s} \right) = (1 - sS)(1 - st/S),$$

where $S$ is defined by (22). This gives

$$R_i = -\frac{S^{i+1}(1 - S)}{t - s^2} \left( \frac{1}{1 - ts/S} - \frac{1}{1 - sS} \right),$$

so that

$$[s^m]R_i = -\frac{S^{i+1-m}(1 - S)}{t - S^2} \left( t^m - S^{2m} \right) = \sum_{j=0}^{m-1} t^{m-1-j} S^{2j+i-m+1} (S - 1).$$

and

$$[s^m t m]R_i = \sum_{j=0}^{m-1} [j+1] S^{2j+i-m+1} (S - 1) = \sum_{j=0}^{m-1} [j+1] S^{2j+i-m+1} (S - 1).$$

The Lagrange inversion gives, for $n \geq 1$ and $k \in \mathbb{Z}$,

$$[t^n] S^k (S - 1) = \begin{cases} 
0 & \text{if } n < k; \\
1 - k z & \text{if } n = k; \\
\frac{1}{n} \sum_{p=1}^{n-k} z^p \binom{n}{p} (n - k - 1) p \left( \frac{n - p - kp}{n - k - 1} \right) & \text{otherwise.}
\end{cases}$$

Returning to (23), this gives

$$[s^m t m]R_i = -(m-i-1) z + \sum_{j=0}^{m-i-2} z^p \sum_{p=1}^{j+1} \binom{j+1}{p} \left( \frac{m - i - j - 1}{p - 1} \right) \frac{j + 1 - p(2j + i - m + 2)}{m - i - j - 1}.\]$$

Proving that $R_i$ is zero boils down to proving, for $1 \leq p \leq m - i$,

$$\sum_{j=0}^{m-i-2} \frac{1}{j+1} \binom{j+1}{p} \left( \frac{m - i - j - 1}{p - 1} \right) \frac{j + 1 - p(2j + i - m + 2)}{m - i - j - 1} = (m - i - 1) \chi_{p=1}.$$
