Specification and Verification in CCS

Catuscia Palamidessi

catuscia@lix.polytechnique.fr

Example: A distributed scheduler

- $1, \dots, n$ are tasks identifiers. Tasks have to be executed repeatedly, in a cyclic order. There can be more than one task executed at the same time, but the next instance of Task i cannot start before previous instance has finished.
- **Specification:** We use:
 - a_k as the signal **start** to Task k and
 - b_k as the signal that Task k has **terminated**
- **Assume:**
 - $X \subseteq \{1, \dots, n\}$ are the tasks in progress
 - Task i is next

$$\text{ScSpec}(i, X) \equiv \sum \{ b_k. \text{ScSpec}(i, X - \{k\}) \mid k \in X \} \quad \text{if } i \in X$$

$$\begin{aligned} \text{ScSpec}(i, X) &\equiv a_i. \text{ScSpec}(i+1, X \cup \{i\}) \\ &+ \\ &\sum \{ b_k. \text{ScSpec}(i, X - \{k\}) \mid k \in X \} \quad \text{if } i \notin X \end{aligned}$$

Example: A distributed scheduler

- **Implementation:** We build the scheduler, Sched, as a ring of n cells each linked to one task

- Cell:

$$A \equiv a.C$$

$$C \equiv c.E$$

$$E \equiv b.D + d.B$$

$$B \equiv b.A$$

$$D \equiv d.A$$

Note: A stands for $A(a,b,c,d)$, B stands for $B(a,b,c,d)$, etc.

We will also use A_k for $A(a_k, b_k, c_k, c_{k-1})$, B_k for $B(a_k, b_k, c_k, c_{k-1})$, etc.

- Definition $\text{Sched} \equiv (\nu c_1) \dots (\nu c_n) (A_1 \mid \prod \{ D_k \mid k \neq 1 \})$
- Theorem 1 (Correctness of the implementation wrt the specification):
 $\text{Sched} = \text{ScSpec}(1, \emptyset)$

Scheduler: Proof of correctness

- The meaning of the various cells:
 - A_i : Task i is next, and it is ready to initiate
 - B_i : Task i is next, but it is not ready to initiate
 - D_i : Task i is not next, but it is ready to initiate
 - E_i : Task i is not next, and it is not ready to initiate

- Definition:

$$\text{Sched}(i,X) \equiv (\forall \mathbf{c}) (B_i \mid \prod \{D_k \mid k \notin X\} \mid \prod \{E_m \mid m \in X - \{i\}\}) \quad \text{if } i \in X$$

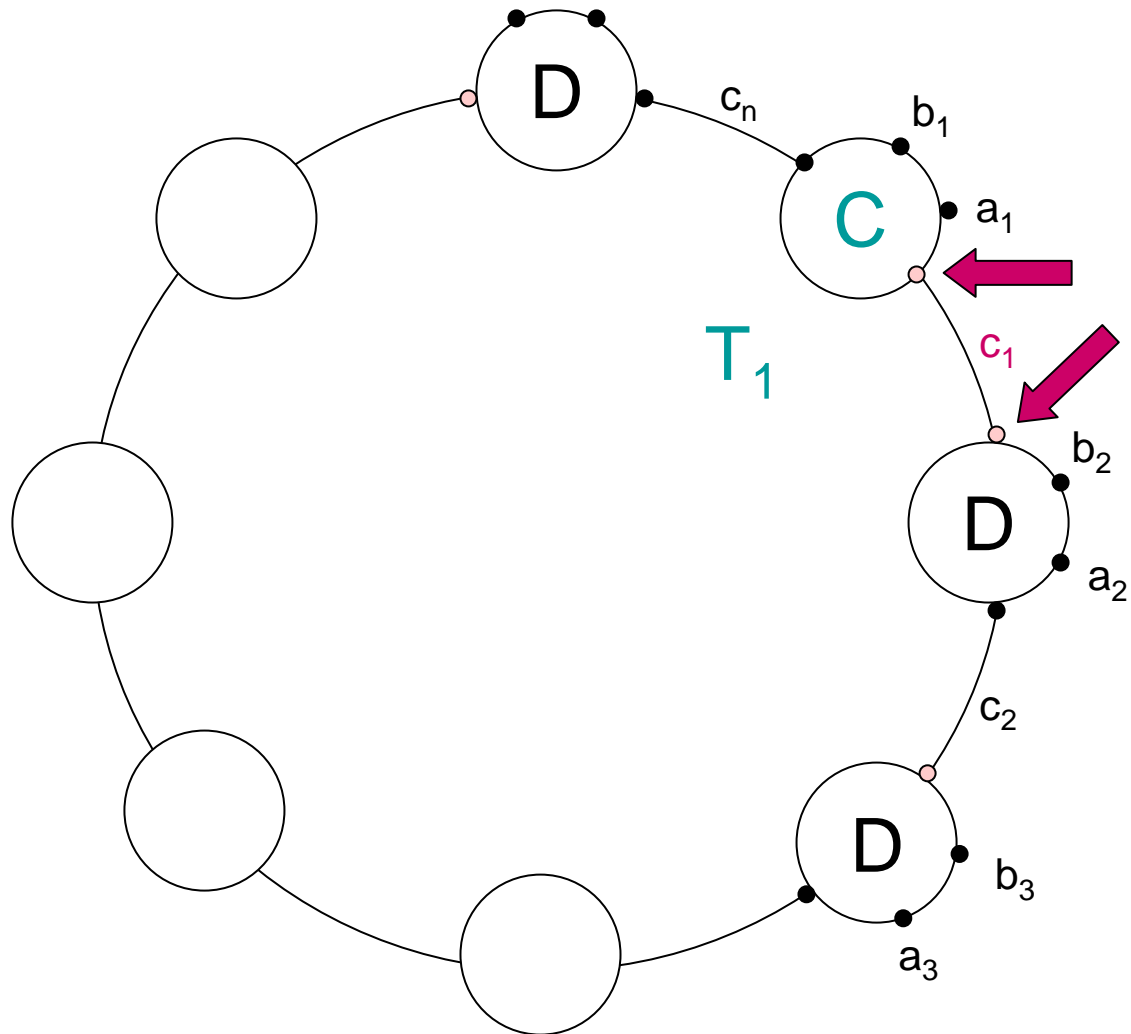

$$\text{Sched}(i,X) \equiv (\forall \mathbf{c}) (A_i \mid \prod \{D_k \mid k \notin X \cup \{i\}\} \mid \prod \{E_m \mid m \in X\}) \quad \text{if } i \notin X$$

- Proposition 2: $\text{Sched}(i,X) = \text{ScSpec}(i,X)$
- Theorem 1 is a particular case of Proposition 2

Implementation of the scheduler: how it works

Implementation of the scheduler: how it works

Implementation of the scheduler: how it works

Implementation of the scheduler: a possible future configuration

Scheduler: Proof of Correctness

Proposition 2: $\text{Sched}(i, X) = \text{ScSpec}(i, X)$

Proof

- Lemma 3

- (1) $(\forall c_i) (C_i \mid D_{i+1}) = \tau.(\forall c_i) (E_i \mid A_{i+1})$
- (2) $(\forall c_i) (C_i \mid E_{i+1}) = \tau.(\forall c_i) (E_i \mid B_{i+1})$

Proof: By expansion law

- Lemma 4

- $\text{Sched}(i, X) = \sum \{ b_k. \text{Sched}(i, X - \{k\}) \mid k \in X \}$ if $i \in X$
- $\text{Sched}(i, X) = a_i. \text{Sched}(i+1, XU\{i\})$
+
 $\sum \{ b_k. \text{Sched}(i, X - \{k\}) \mid k \in X \}$ if $i \notin X$

Proof: By Expansion law and Lemma 3

From Lemma 4 and the Definition law we obtain that $\text{Sched}(i, X) = \text{ScSpec}(i, X)$ □

Example: Counter

- It is possible in CCS to create structures which grow and shrink dynamically. Examples include unbounded queues and stacks, and counters.

- Specification of a Counter

A counter is an object that can be

- tested for zero zero
- incremented inc
- decremented dec

$\text{Count}_0 \equiv \text{inc.Count}_1 + \text{zero.Count}_0$

$\text{Count}_n \equiv \text{inc.Count}_{n+1} + \text{dec.Count}_{n-1} \quad n > 0$

Example: Counter

- Implementation: A structure obtained by linking together a process B and n copies of a process C specified as follows:

$$B \equiv \text{inc.}(B \hat{C}) + \text{zero.B}$$

$$C \equiv \text{inc.}(C \hat{C}) + \text{dec.D}$$

$$D \equiv \underline{d}.C + \underline{z}.B$$

$$P \hat{Q} \equiv (\nu i')(\nu z')(\nu d') (P(z,d,i',z',d') \mid Q(z',d', \text{inc}, \text{zero}, \text{dec}))$$

Note: B, C and D stand for $B(z,d,\text{inc},\text{zero},\text{dec})$, $C(z,d,\text{inc},\text{zero},\text{dec})$, and $D(z,d,\text{inc},\text{zero},\text{dec})$ respectively.

$(P \hat{Q})$ stands for $(P \hat{Q})(z,d,\text{inc},\text{zero},\text{dec})$.

Proposition: $\hat{}$ is associative, i.e. $P \hat{(Q \hat{R})} = (P \hat{Q}) \hat{R}$

Example: Counter

- Implementation:

Definition: $C^{(n)} \equiv B \wedge C \wedge C \dots \wedge C$ (n times)

- Theorem (Correctness): $C^{(n)} = \text{Count}_n$

Proof

Lemma: (1) $C \wedge D \approx D \wedge C$
(2) $B \wedge D \approx B \wedge B$
(3) $B \wedge B = B$

We can now prove that

- $C^{(0)} = \text{inc. } C^{(1)} + \text{zero. } C^{(0)}$ and

- $C^{(n)} = C^{(n-1)} \wedge C$ for $n > 0$
= $\text{inc. } (C^{(n-1)} \wedge C \wedge C) + \text{dec. } (C^{(n-1)} \wedge D)$
= $\text{inc. } C^{(n+1)} + \text{dec. } C^{(n-1)}$

by definition
by expansion law
by the lemma above

Hence $C^{(n)}$ satisfies the same equations as Count_n . By the unique solution law we can conclude $C^{(n)} = \text{Count}_n$ \square
