

Large-scale Mathematical Optimization

Leo Liberti, CNRS LIX Ecole Polytechnique
`liberti@lix.polytechnique.fr`

INF580

About the course

- ▶ **Aims of lectures:** theory, algorithms, some code
won't repeat much of MAP557
- ▶ **Aims of TD:** modelling abilities in practice
with AMPL and Python
- ▶ **Warning:**

<i>some disconnection between lectures and TD is normal</i>

some theoretical topics do not lend themselves to implementation
- ▶ Lectures/TD: (generally) on fri afternoon
- ▶ **Exam:** mini-project (individual/pairs) or oral exam

<http://www.lix.polytechnique.fr/~liberti/teaching/dix/inf580>

Outline

Introduction

- MP language
- Solvers
- MP systematics
- Some applications

Decidability

- Formal systems
- Gödel
- Turing
- Tarski
- Completeness and incompleteness
- MP solvability

Efficiency and Hardness

- Some combinatorial problems in **NP**
- NP**-hardness
- Complexity of solving MP formulations

Distance Geometry

- The universal isometric embedding
- Dimension reduction
- Dealing with incomplete metrics
- The Isomap heuristic
- Distance geometry problem
- Distance geometry in MP
- DGP cones
- Barvinok's Naive Algorithm
- Isomap revisited

Summary

Random projections in LP

- Random projection theory
- Projecting LP feasibility
- Projecting LP optimality
- Solution retrieval
- Application to quantile regression

Sparsity and ℓ_1 minimization

- Motivation
- Basis pursuit
- Theoretical results
- Application to noisy channel encoding
- Improvements

Kissing Number Problem

- Lower bounds
- Upper bounds from SDP?
- Gregory's upper bound
- Delsarte's upper bound
- Pfender's upper bound

Clustering in Natural Language

- Clustering on graphs
- Clustering in Euclidean spaces
- Distance instability
- MP formulations
- Random projections again

Clustering in Natural Language

- Clustering on graphs
- Clustering in Euclidean spaces
- Distance instability
- MP formulations
- Random projections again

What is *Mathematical Optimization*?

- ▶ Mathematics of solving optimization problems
- ▶ Formal language: Mathematical Programming (MP)
- ▶ Sentences: descriptions of optimization problems
- ▶ Interpreted by solution algorithms (“solvers”)
- ▶ As expressive as any imperative language
- ▶ Shifts focus from *algorithmics* to *modelling*

Why *Large-scale*?

- ▶ Any process can be optimized
- ▶ Social, technical and business processes are complex
- ▶ Computer power limits model precision
- ▶ Nowadays, need to solve very precise models
⇒ *increase in model size*
- ▶ ⇒ algorithmic complexity must grow slowly with size
- ▶ Focus on LP algs and heuristics
- ▶ Investigate LP relaxations & dimensionality reduction methods

The syllabus

- ▶ Which optimization problems can be solved?
a tour of 20th century logic
- ▶ Complexity of optimization problems
basics of theoretical computer science
- ▶ Distance geometry
modern large-scale optimization and data science techniques
- ▶ Random projections
new approaches to approximately solving large-scale problems
- ▶ Sparsity and ℓ_1 minimization
integrality out of continuity
- ▶ Further topics
as time allows

MP Formulations

Given functions $f, g_1, \dots, g_m : \mathbb{Q}^n \rightarrow \mathbb{Q}$ and $Z \subseteq \{1, \dots, n\}$

$$\left. \begin{array}{l} \min_x f(x) \\ \forall i \leq m \quad g_i(x) \leq 0 \\ \forall j \in Z \quad x_j \in \mathbb{Z} \end{array} \right\} [P]$$

► More general than it looks:

- $\max f(x) = -\min -f(x)$
- $g_i(x) = 0 \Leftrightarrow (g_i(x) \leq 0 \wedge -g_i(x) \leq 0)$
- $L \leq x \leq U \Leftrightarrow (L - x \leq 0 \wedge x - U \leq 0)$

► f, g_i represented by *expression DAGs*

Class of all formulations P : MIP

Semantics of MP formulations

- ▶ $\llbracket P \rrbracket$ = optimum (or optima) of P
- ▶ Given $P \in \text{MIP}$, there are three possibilities:
 $\llbracket P \rrbracket$ exists, P is unbounded, P is infeasible
- ▶ P is feasible iff $\llbracket P \rrbracket$ exists or P is unbounded
otherwise it is infeasible
- ▶ P has an optimum iff $\llbracket P \rrbracket$ exists
otherwise it is infeasible or unbounded
- ▶ Example:

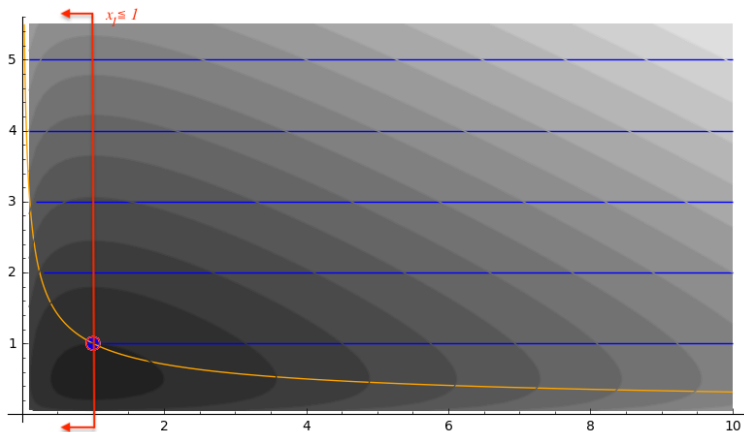

$$\left. \begin{array}{ll} \min & x_1 + 2x_2 - \log(x_1 x_2) \\ & x_1 x_2^2 \geq 1 \\ & x_1 \in [0, 1] \\ & x_2 \in \mathbb{N} \end{array} \right\}$$

Exercise

Code this toy MP in AMPL and solve it with BARON

Example: solution “by inspection”

$$P \equiv \min\{x_1 + 2x_2 - \log(x_1x_2) \mid x_1x_2^2 \geq 1 \wedge 0 \leq x_1 \leq 1 \wedge x_2 \in \mathbb{N}\}$$

$$\llbracket P \rrbracket = (\text{opt}(P), \text{val}(P))$$

$$\text{opt}(P) = (1, 1)$$

$$\text{val}(P) = 3$$

Feasibility and optimality

- ▶ Feasibility problem: $[g(x) \leq 0]$
can be written as the MP $[\min\{0 \mid g(x) \leq 0\}]$
- ▶ Bounded MP $[\min\{f(x) \mid g(x) \leq 0\}]$:
bisection on f_0 in feas. prob. $[f(x) \leq f_0 \wedge g(x) \leq 0]$
- ▶ Unbounded MP: not equivalent to feasibility
in general, cannot prove unboundedness

Bisection algorithm

- ▶ $P \equiv \min\{f(x) \mid \forall i \in I g_i(x) \leq 0 \wedge x \in X\}$
- ▶ Assume global opt x^* of P has value $f(x^*)$ between given lower/upper bounds
- ▶ Reformulate P to a parametrized feasibility problem $Q(f_0) \equiv \{x \in X \mid f(x) \leq f_0 \wedge \forall i \in I g_i(x) \leq 0\}$

Bisection algorithm for *optimal value*

- 1: *Input*: lower & upper bound for f_0
- 2: **while** lower and upper bounds differ by $> \epsilon$ **do**
- 3: let f_0 be midway between bounds
- 4: **if** $Q(f_0)$ is feasible **then**
- 5: update *upper bound* to f_0
- 6: **else**
- 7: update *lower bound* to f_0
- 8: **end if**
- 9: **end while**

- ▶ solve an optimization problem with calls to feasibility oracle
- ▶ need only $\lceil \log_2 \left(\frac{\text{UB}-\text{LB}}{\epsilon} \right) \rceil$ calls to oracle

Exercise

Solve the toy MP using this bisection algorithm in AMPL

Bisection algorithm for *optimum*

- 1: *Input:* lower & upper bounds for f_0 ,
candidate global optimum \hat{x}
- 2: **while** lower and upper bounds differ by $> \epsilon$ **do**
- 3: let f_0 be midway between bounds
- 4: **if** $Q(f_0)$ is feasible **then**
- 5: find a feasible point x'
- 6: **if** $f(x')$ better than $f(\hat{x})$ **then**
- 7: update \hat{x} to x'
- 8: update *upper* bound to $f(\hat{x})$
- 9: **end if**
- 10: **else**
- 11: update *lower* bound to f_0
- 12: **end if**
- 13: **end while**

Exercise

Solve the toy MP using this bisection algorithm in AMPL

Bisection algorithm for MP (formal)

Given:

- ▶ an optimization problem in *minimization* form
for maximization have to switch a few things: which ones?
- ▶ global optimal value approximation tolerance $\epsilon > 0$
- ▶ lower bound \underline{f} , upper bound \bar{f}
- ▶ a feasibility algorithm \mathcal{F} which
finds an element in a set or certifies emptiness up to ϵ

Bisection algorithm for MP (formal)

```
1: let  $(\hat{x}, \hat{f}) = (\text{uninitialized}, \bar{f})$ 
2: while  $\bar{f} - \underline{f} > \epsilon$  do
3:   let  $f_0 = (\underline{f} + \bar{f})/2$ 
4:    $(x', f') = \mathcal{F}(Q(f_0))$ 
5:   if  $(x', f') \neq (\emptyset, \emptyset)$  then
6:     if  $f' < \hat{f}$  then
7:       update  $(\hat{x}, \hat{f}) \leftarrow (x', f')$ 
8:       update  $\bar{f} \leftarrow \hat{f}$ 
9:     end if
10:  else
11:    update  $\underline{f} \leftarrow f_0$ 
12:  end if
13: end while
```

Subsection 1

MP language

Entities of a MP formulation

- ▶ Sets of indices
- ▶ Parameters
problem input, or *instance*
- ▶ Decision variables
will encode the solution after solver execution
- ▶ Objective function
- ▶ Constraints

MP Example

Linear Program (LP) in standard form

- ▶ m, n : number of rows and columns
corresponding index sets $I = \{1, \dots, m\}, J = \{1, \dots, n\}$
- ▶ $c \in \mathbb{R}^n, b \in \mathbb{R}^m, A$ an $m \times n$ matrix
- ▶ $x \in \mathbb{R}^n$
- ▶ $\min_x c^\top x$
- ▶ $Ax = b \quad \wedge \quad x \geq 0$

Exercise

Code this example in AMPL and solve it with CPLEX

MP language implementations

- ▶ Humans model with quantifiers (\forall, \sum, \dots)

e.g. $\forall i \in I \sum_{j \in J} a_{ij} x_j \leq b_i$

structured formulation

- ▶ Solution algorithms accept lists of explicit constraints

e.g. $4x_1 + 1.5x_2 + x_6 \leq 2$

flat formulation

- ▶ Translation from **structured** to **flat** formulation

- ▶ MP language implementations

AMPL, GAMS, Matlab+YALMIP,

Python+amplpy/cvxpy, Julia+JuMP, ...

Exercise

Use AMPL to derive the flat formulation from the standard form LP

AMPL

- ▶ AMPL = A Mathematical Programming Language
- ▶ Syntax similar to human notation
- ▶ Bare-bone programming language
e.g. no function calls
- ▶ Commercial & closed-source
 - ▶ extremely rapid prototyping
 - ▶ we get free licenses for this course
 - ▶ free open-source AMPL sub-dialect in GLPK `glpsol`
- ▶ Can also use Python+`amplpy/cvxpy`, or Julia+`JuMP`

Exercise

Formulate and solve the standard form LP using Python+`amplpy`

Subsection 2

Solvers

Solvers

- ▶ Solver:
a solution algorithm for a whole subclass of MP
examples: BARON, CPLEX
- ▶ Take formulation P as input
- ▶ Output $\llbracket P \rrbracket$ *and possibly other information*
- ▶ Trade-off between generality and efficiency
fast solvers for large MP subclasses: unlikely

Some subclasses of MP

(i) LINEAR PROGRAMMING (LP)

f, g_i linear, $Z = \emptyset$

(ii) MIXED-INTEGER LP (MILP)

f, g_i linear, $Z \neq \emptyset$

(iii) NONLINEAR PROGRAMMING
(NLP)

some nonlinearity in f, g_i , $Z = \emptyset$

f, g_i convex: convex NLP (cNLP)

(iv) MIXED-INTEGER NLP
(MINLP)

some nonlinearity in f, g_i , $Z \neq \emptyset$

f, g_i convex: convex MINLP

(cMINLP)

$$\left. \begin{array}{l} \min \quad f(x) \\ \forall i \leq m \quad g_i(x) \leq 0 \\ \forall j \in Z \quad x_j \in \mathbb{Z} \end{array} \right\} [P]$$

And their solvers

- (i) **LINEAR PROGRAMMING (LP)**
simplex algorithm, interior point method (IPM)
Implementations: CPLEX, GLPK, CLP
- (ii) **MIXED-INTEGER LP (MILP)**
cutting plane alg., Branch-and-Bound (BB)
Implementations: CPLEX, GuRoBi
- (iii) **NONLINEAR PROGRAMMING (NLP)**
IPM, gradient descent (cNLP), spatial BB (sBB)
Implementations: IPOPT (cNLP), Baron, Couenne
- (iv) **MIXED-INTEGER NLP (MINLP)**
outer approximation (cMINLP), sBB
Implementations: Bonmin (cMINLP), Baron, Couenne

Subsection 3

MP systematics

Types of MP

Continuous variables:

- ▶ LP (linear functions)
- ▶ QP (quadratic objective over affine sets)
- ▶ QCP (linear objective over quadratic sets)
- ▶ QCQP (quadratic objective over quadratic sets)
- ▶ cNLP (convex sets, convex objective)
- ▶ SOCP (LP over 2nd order cone)
- ▶ SDP (LP over PSD cone)
- ▶ CPP (LP over copositive cone)
- ▶ NLP (nonlinear functions)

Types of MP

Mixed-integer variables:

- ▶ IP (integer programming), MIP (mixed-integer programming)
- ▶ *extensions:* MILP, MIQP, MIQCP, MIQCQP, cMINLP, MINLP
- ▶ BLP (LP over $\{0, 1\}^n$)
- ▶ BQP (QP over $\{0, 1\}^n$)

Some more “exotic” classes:

- ▶ MOP (multiple objective functions)
- ▶ BLvP (optimization constraints)
- ▶ SIP (semi-infinite programming)

Example: nonlinear constraint $y \geq x^2$ equivalent to infinite linear constraint set $\forall p \in \mathbb{R} (y \geq 2px - p^2)$

Subsection 4

Some applications

Some application fields

- ▶ Production industry
planning, scheduling, allocation, ...
- ▶ Transportation & logistics
facility location, routing, rostering, ...
- ▶ Service industry
pricing, strategy, product placement, ...
- ▶ Energy industry
power flow optimization, monitoring smart grids, ...
- ▶ Machine Learning & Artificial Intelligence
clustering, support vector machines, ANN training, ...
- ▶ Biochemistry & medicine
protein structure, blending, tomography, ...
- ▶ Mathematics
Kissing number, packing of geometrical objects, ...

Easy example

A bank needs to invest C gazillion dollars, and focuses on two types of investments: one, imaginatively called (a), guarantees a 15% return, while the other, riskier and called, surprise surprise, (b), is set to a 25%. At least one fourth of the budget C must be invested in (a), and the quantity invested in (b) cannot be more than double the quantity invested in (a). How do we choose how much to invest in (a) and (b) so that revenue is maximized?

Modelling school

First question to ask oneself is: **What are the decision variables?**

Easy example

- ▶ Parameters:

- ▶ budget C
- ▶ return on investment on (a): 15%, on (b): 25%

- ▶ Decision variables:

- ▶ x_a = budget invested in (a)
- ▶ x_b = budget invested in (b)

- ▶ Objective function: $1.15 x_a + 1.25 x_b$

- ▶ Constraints:

- ▶ $x_a + x_b = C$
- ▶ $x_a \geq C/4$
- ▶ $x_b \leq 2x_a$

Easy example: remarks

- ▶ *Missing trivial constraints:*

verify that $x_a = C + 1$, $x_b = -1$ satisfies constraints
forgot $x \geq 0$

- ▶ *No numbers in formulations:*

replace numbers by parameter symbols

$$\left. \begin{array}{l} \max_{x_a, x_b \geq 0} \quad c_a x_a + c_b x_b \\ \quad \quad \quad x_a + x_b = C \\ \quad \quad \quad x_a \geq pC \\ \quad \quad \quad dx_a - x_b \geq 0 \end{array} \right\}$$

- ▶ *Formulation generality:*

extend to n investments:

$$\left. \begin{array}{l} \max_{x \geq 0} \quad \sum_{j \leq n} c_j x_j \\ \quad \quad \quad \sum_{j \leq n} x_j = C \\ \quad \quad \quad x_1 \geq pC \\ \quad \quad \quad dx_1 - x_2 \geq 0 \end{array} \right\}$$

- ▶ *Every parameter needs a numeric value:* e.g. $C = 1$

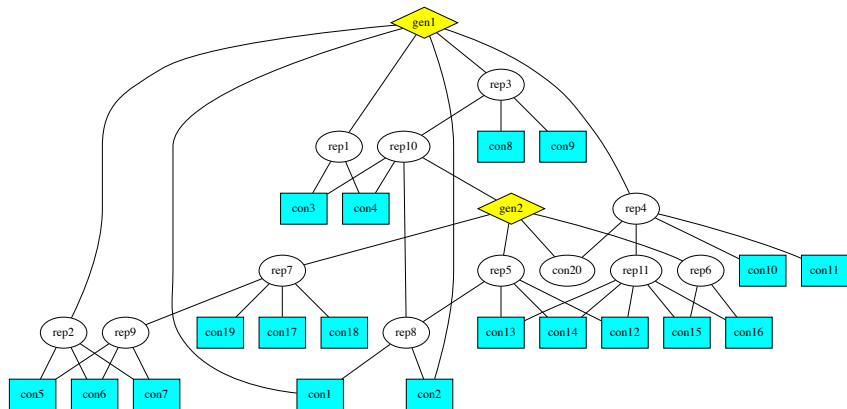

Example: monitoring an electrical grid

An electricity distribution company wants to **monitor** certain quantities at the **lines** of its grid by placing **measuring devices** at the buses. There are three types of buses: **consumer, generator, and repeater**. There are **five types of devices**:

- ▶ A: installed at any bus, and monitors all incident lines (cost: 0.9MEUR)
- ▶ B: installed at consumer and repeater buses, and monitors two incident lines (cost: 0.5MEUR)
- ▶ C: installed at generator buses only, and monitors one incident line (cost: 0.3MEUR)
- ▶ D: installed at repeater buses only, and monitors one incident line (cost: 0.2MEUR)
- ▶ E: installed at consumer buses only, and monitors one incident line (cost: 0.3MEUR).

Provide a **least-cost installation plan** for the devices at the buses, so that **all lines are monitored** by at least one device.

Example: the electrical grid

Example: formulation

- ▶ Index sets:
 - ▶ V : set of buses v
 - ▶ E : set of lines $\{u, v\}$
 - ▶ A : set of *directed* lines (u, v)
 - ▶ $\forall u \in V$ let $N_u =$ buses adjacent to u
 - ▶ D : set of device types
 - ▶ D_M : device types covering > 1 line
 - ▶ $D_1 = D \setminus D_M$
- ▶ Parameters:
 - ▶ $\forall v \in V$ $b_v =$ bus type
 - ▶ $\forall d \in D$ $c_d =$ device cost

Example: formulation

▶ Decision variables

- ▶ $\forall d \in D, v \in V \quad x_{dv} = 1$
iff device type d installed at bus v
- ▶ $\forall d \in D, (u, v) \in A \quad y_{duv} = 1$
iff device type d installed at bus u measures line $\{u, v\}$
- ▶ all variables are binary

▶ Objective function

$$\min_{x,y} \sum_{d \in D} \sum_{v \in V} c_d x_{dv}$$

Example: formulation

► Constraints

- device types:

$$\forall v \in V \quad b_v = \text{gen} \quad \rightarrow \quad x_{Bv} = 0$$

$$\forall v \in V \quad b_v \in \{\text{con}, \text{rep}\} \quad \rightarrow \quad x_{Cv} = 0$$

$$\forall v \in V \quad b_v \in \{\text{gen}, \text{con}\} \quad \rightarrow \quad x_{Dv} = 0$$

$$\forall v \in V \quad b_v \in \{\text{gen}, \text{rep}\} \quad \rightarrow \quad x_{Ev} = 0$$

- at most one device of any type at each bus

$$\forall v \in V \quad \sum_{d \in D} x_{dv} \leq 1$$

Example: formulation

► Constraints

- A: every line incident to installed device is monitored

$$\forall u \in V, v \in N_u \quad y_{Auv} = x_{Au}$$

- B: two monitored lines incident to installed device

$$\forall u \in V \quad \sum_{v \in N_u} y_{Buv} = \min(2, |N_u|)x_{Bu}$$

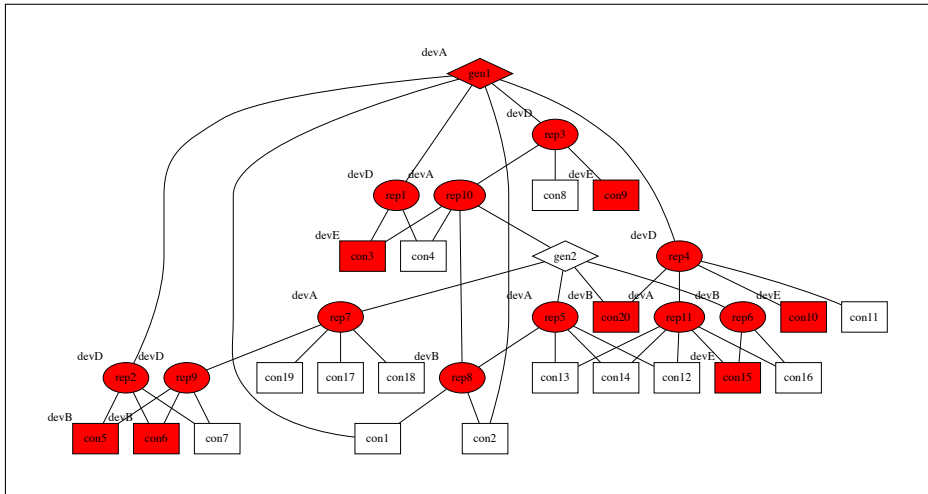

- C,D,E: one monitored line incident to installed device

$$\forall d \in D_1, u \in V \quad \sum_{v \in N_u} y_{duv} = x_{du}$$

- line is monitored

$$\forall \{u, v\} \in E \quad \sum_{d \in D} y_{duv} + \sum_{e \in D} y_{evu} \geq 1$$

Example: solution

all lines monitored, no redundancy, cost 9.2MEUR

Outline

Introduction

- MP language
- Solvers
- MP systematics
- Some applications

Decidability

- Formal systems
- Gödel
- Turing
- Tarski
- Completeness and incompleteness
- MP solvability

Efficiency and Hardness

- Some combinatorial problems in NP
- NP-hardness
- Complexity of solving MP formulations

Distance Geometry

- The universal isometric embedding
- Dimension reduction
- Dealing with incomplete metrics
- The Isomap heuristic
- Distance geometry problem
- Distance geometry in MP
- DGP cones
- Barvinok's Naive Algorithm
- Isomap revisited

Summary

Random projections in LP

- Random projection theory
- Projecting LP feasibility
- Projecting LP optimality
- Solution retrieval
- Application to quantile regression

Sparsity and ℓ_1 minimization

- Motivation
- Basis pursuit
- Theoretical results
- Application to noisy channel encoding
- Improvements

Kissing Number Problem

- Lower bounds
- Upper bounds from SDP?
- Gregory's upper bound
- Delsarte's upper bound
- Pfender's upper bound

Clustering in Natural Language

- Clustering on graphs
- Clustering in Euclidean spaces
- Distance instability
- MP formulations
- Random projections again

Can we solve MPs?

- ▶ “Solve MPs”: is there an algorithm \mathcal{D} s.t.:

$$\forall P \in \text{MIP} \quad \mathcal{D}(P) = \begin{cases} \text{infeasible} & P \text{ is infeasible} \\ \text{unbounded} & P \text{ is unbounded} \\ \llbracket P \rrbracket & \text{otherwise} \end{cases}$$

- ▶ I.e. does there exist a single, all-powerful solver?

Subsection 1

Formal systems

Formal systems (FS)

- ▶ A *formal system* consists of:
 - ▶ an *alphabet*
 - ▶ a *formal grammar*
allowing the determination of *formulae* and *sentences*
 - ▶ a set A of *axioms* (given sentences)
 - ▶ a set R of *inference rules*
allowing the derivation of new sentences from old ones
- ▶ A *theory* T is the smallest set of sentences that is obtained by recursively applying R to A

[Smullyan, Th. of Formal Systems, 1961]

Examples

► *Alphabets:*

$$\mathcal{B} = \{_, 0, 1\}, \mathcal{N} = \mathcal{B} \cup \{2, 3, \dots\}, \mathcal{V} = \{x_0, x_1, x_2, \dots\}$$

$$\mathcal{E} = \{(_, _), +, -, \times, \div, \square^\square, \exp, \log, \sin\} \cup \mathcal{N} \cup \mathcal{V}$$

$$\mathcal{PA}_1 = \{\forall, \exists, \vee, \wedge, \neg, =\} \cup \mathcal{E},$$

$$\mathcal{MP} = \{\min, \max, \sum, \prod, \leq, \geq\} \cup \mathcal{PA}_1$$

► *An expression grammar:*

$$\begin{aligned} \text{expr} &: \text{term} + \text{expr} \quad | \quad \text{term} - \text{expr} \quad | \quad \text{term} \\ \text{term} &: \text{factor} \times \text{term} \quad | \quad \text{factor} \div \text{term} \quad | \quad \text{factor} \\ \text{factor} &: \text{power}^{\text{power}} \quad | \quad \text{power} \\ \text{power} &: \log(\text{unr}) \quad | \quad \exp(\text{unr}) \quad | \quad \sin(\text{unr}) \quad | \quad (-\text{unr}) \quad | \quad \text{unr} \\ \text{unr} &: (\text{expr}) \quad | \quad \mathcal{N} \quad | \quad \mathcal{V} \end{aligned}$$

e.g. $(1 - \sin(x)^2)^{(1/2)}$: $\text{expr} = \text{term} \rightarrow \text{factor} \rightarrow \text{power}^{\text{power}} \rightarrow$
 $\text{unr}^{\text{unr}} \rightarrow (\text{expr})^{(\text{expr})} \rightarrow (\text{term} - \text{expr})^{(\text{term})} \rightarrow$
 $(\text{factor} - \text{term})^{(\text{factor} \div \text{factor})} \rightarrow \dots$

► *Axioms:* see later

► *Inference rules:*

modus ponens, symbol replacement, $A \vdash A \wedge A$, $A \vdash A \vee A$, ...

Example: PA1

- ▶ **Theory:** 1st order provable sentences about \mathbb{N}
- ▶ **Alphabet:** $+, \times, \wedge, \vee, \rightarrow, \forall, \exists, \neg, =, 0, S(\cdot)$ and variable names
- ▶ **Peano's Axioms:**

1. $\forall x (0 \neq S(x))$
2. $\forall x, y (S(x) = S(y) \rightarrow x = y)$
3. $\forall x (x + 0 = x)$
4. $\forall x (x \times 0 = 0)$
5. $\forall x, y (x + S(y) = S(x + y))$
6. $\forall x, y (x \times S(y) = x \times y + x)$
7. axiom schema over all $(k + 1)$ -ary ϕ : $\forall y = (y_1, \dots, y_k) (\phi(0, y) \wedge \forall x (\phi(x, y) \rightarrow \phi(S(x), y))) \rightarrow \forall x \phi(x, y)$

- ▶ **Inference:** see

https://en.wikipedia.org/wiki/List_of_rules_of_inference

e.g. *modus ponens* $(P \wedge (P \rightarrow Q)) \rightarrow Q$

- ▶ **Generates ring $(\mathbb{N}, +, \times)$ and arithmetical proofs**
e.g. $\exists x \in \mathbb{N}^n \forall i (p_i(x) \leq 0)$ (polynomial MINLP feasibility)

Example of PA1 derivation

Thm.

$$\forall x (x = x)$$

Proof

A3	$\forall x$	$x + 0 = x$	[1]
logic	$\forall t, r, s$	$t = r \rightarrow (t = s \rightarrow r = s)$	[2]
1, 2	$\forall x$	$x + 0 = x \rightarrow (x + 0 = x \rightarrow x = x)$	[3]
1, 3, mp	$\forall x$	$x + 0 = x \rightarrow x = x$	[4]
1, 4, mp	$\forall x$	$x = x$	QED

Notes:

- ▶ truth tables of $A \rightarrow B$ and $(\neg A) \vee B$ are the same
- ▶ logic indicates a “logical theorem”
[equality] $(t = r \wedge t = s) \rightarrow r = s$; [truth tables] $t = r \rightarrow (t = s \rightarrow r = s)$
- ▶ mp indicates application of *modus ponens*
- ▶ all derivations are completely syntactical

Example: Reals

- ▶ **Theory:** 1st order provable sentences about \mathbb{R}
- ▶ **Alphabet:** $+, \times, \wedge, \vee, \forall, \exists, =, <, \leq, 0, 1$, variable names
- ▶ **Axioms:** field and order
- ▶ **Inference:** see
https://en.wikipedia.org/wiki/List_of_rules_of_inference
e.g. *modus ponens* $(P \wedge (P \rightarrow Q)) \rightarrow Q$
- ▶ **Generates polynomial rings** $\mathbb{R}[X_1, \dots, X_k]$ (for all k)
e.g. $\exists x \in \mathbb{R}^n \forall i (p_i(x) \leq 0)$ (polynomial NLP feasibility)

Phrases and sentences

- ▶ **Phrase**: sequence of symbols generated by FS grammar
e.g. x , $S(x)$, $x + 0 = x$, $x \times y = z$
- ▶ **Sentence**: phrase, with no unquantified variable symbol, stating a relation between variables
e.g. $\forall x (x + 0 = x)$, $\forall x, y \exists z (x + y = z)$
- ▶ Only sentences can be *decidable, provable* (or *not* –)

Relevance of FSs to MP

Given a FS \mathcal{F} :

- ▶ A *decision problem* is a set P of sentences
Decide if a given sentence f belongs to P
- ▶ Decidability in formal systems:
 $P \equiv$ provable sentences
- ▶ *Proof of f* : finite sequence of sentences ending with f
sentences: **axioms**, or derived from predecessors by **inference rules**
- ▶ **PA1**: decide if sentence f about \mathbb{N} has a proof
e.g. $\exists x \in \mathbb{Z}^n \forall i p_i(x) \leq 0$ (polynomial p)
- ▶ **Reals**: decide if sentence f about \mathbb{R} has a proof
e.g. $\exists x \in \mathbb{R}^n \forall i p_i(x) \leq 0$ (polynomial p)
- ▶ Formal study of MINLP/NLP feasibility

Decidability, computability, solvability

- ▶ *Decidability*: applies to decision problems
- ▶ *Computability*: applies to function evaluation
 - ▶ Is the function mapping i to the i -th prime integer computable?
 - ▶ Is the function mapping Cantor's "Continuum Hypothesis" to 1 if provable in the ZFC axiom system, and to 0 otherwise, computable?
- ▶ *Solvability*: applies to other problems
E.g. to optimization problems

Completeness and decidability

▶ *Complete* FS \mathcal{F} :

for any $f \in \mathcal{F}$, either f or $\neg f$ is provable
otherwise \mathcal{F} is *incomplete*

▶ *Decidable* FS \mathcal{F} :

\exists algorithm \mathcal{D} s.t.

$$\forall f \in \mathcal{F} \begin{cases} \mathcal{D}(f) = 1 & \text{iff } f \text{ is provable} \\ \mathcal{D}(f) = 0 & \text{iff } f \text{ is not provable} \end{cases}$$

otherwise \mathcal{F} is *undecidable*

Example: PA1

- ▶ Gödel's 1st incompleteness theorem:
PA1 is incomplete
- ▶ Turing's theorem:
PA1 is undecidable
- ▶ \Rightarrow PA1 is incomplete and undecidable

Subsection 2

Gödel

Gödel's 1st incompleteness theorem

- ▶ \mathcal{F} : any FS extending PA1

- ▶ **Thm.** \mathcal{F} complete iff inconsistent

- ▶ ϕ : sentence “ ϕ not provable in \mathcal{F} ”

denoted $\mathcal{F} \nVdash \phi$; it can be constructed in \mathcal{F} (hard part of thm.)

- ▶ \vdash : “is provable” in PA1; \vdash : in meta-language
- ▶ *Assume \mathcal{F} is complete:* either $\mathcal{F} \vdash \phi$ or $\mathcal{F} \vdash \neg\phi$
- ▶ If $\mathcal{F} \vdash \phi$ then $\mathcal{F} \vdash (\mathcal{F} \nVdash \phi)$ i.e. $\mathcal{F} \nVdash \phi$, contradiction
- ▶ If $\mathcal{F} \vdash \neg\phi$ then $\mathcal{F} \vdash \neg(\mathcal{F} \nVdash \phi)$ i.e. $\mathcal{F} \vdash (\mathcal{F} \vdash \phi)$
this implies $\mathcal{F} \vdash \phi$, i.e. $\mathcal{F} \vdash (\phi \wedge \neg\phi)$, \mathcal{F} inconsistent
- ▶ *Assume \mathcal{F} is inconsistent:*

Then any sentence is provable, i.e. \mathcal{F} complete

Proof: if \mathcal{F} is inconsistent then for some P we have $P \wedge \neg P$;
hence P and $\neg P$ both hold; since P , then for any Q we have $P \vee Q$;
but since $\neg P$, then $P \vee Q$ implies that Q holds; therefore $P \wedge \neg P \rightarrow Q$

- ▶ If we want PA1 to be consistent, it must be incomplete
- ▶ **Warning:** $\mathcal{F} \nVdash \phi \equiv \neg(\mathcal{F} \vdash \phi) \not\equiv \mathcal{F} \vdash \neg\phi$

Gödel's encoding

- ▶ For ψ a phrase in PA1, $\ulcorner \psi \urcorner \in \mathbb{N}$
an integer which encodes the phrase
called "Gödel number" of the phrase
- ▶ $\ulcorner \cdot \urcorner$ is an injective map
many ways to define $\ulcorner \cdot \urcorner$
- ▶ Inverse: $\langle \ulcorner \phi \urcorner \rangle = \phi$
 ϕ is the phrase corresponding to Gödel number $\ulcorner \phi \urcorner$
- ▶ Encode/decode in \mathbb{N} any phrase of a formal system

Gödel's self-referential sentence ϕ

- ▶ For integers x, y $\boxed{\exists g \in \mathbb{N} \langle g \rangle \equiv}$ **proof**(x, y) :
 $\langle g \rangle$ is the sentence “ $\langle x \rangle$ is a proof in PA1 of the sentence $\langle y \rangle$ ”
- ▶ For integers m, n, p $\boxed{\exists g \in \mathbb{N} g =}$ **sost**(m, n, p) =
 g encodes the phrase obtained by replacing in the phrase $\langle m \rangle$ the variable **symbol** with Gödel number n with the Gödel **number** p
[this essentially replaces a symbol with a number in a phrase]
- ▶ Let y be the Gödel number of the phrase “ y ”, i.e. $y = \ulcorner y \urcorner$
- ▶ Define $\gamma(y) \equiv \neg \exists x \in \mathbb{N} \text{proof}(x, \text{sost}(y, y, y))$:
 $\forall y \gamma(y)$: there is no proof in PA1 for the sentence obtained by replacing, in the sentence $\langle y \rangle$, every variable symbol “ y ” with the Gödel number of the phrase “ y ”
- ▶ let $q = \ulcorner \gamma(y) \urcorner$, consider $\phi \equiv \gamma(q)$
note $\phi \equiv \neg \exists x \in \mathbb{N} \text{proof}(x, \text{sost}(q, y, q))$
 q is a symbol denoting a Gödel number $\in \mathbb{N}$, and y is a variable symbol ranging over \mathbb{N} :
no “type mismatch”

Gödel's self-referential sentence ϕ

$$\phi \equiv \neg \exists x \in \mathbb{N} \text{proof}(x, \text{sost}(q, y, q))$$

- ▶ Let $\ulcorner \psi \urcorner \equiv \text{sost}(q, y, q)$

ψ derived by replacing the phrase “ y ” in $\langle q \rangle$ with q

- ▶ $\phi \equiv$ “there is no proof in PA1 for the sentence ψ ”

- ▶ How did we obtain ϕ ? Since $\phi \equiv \gamma(q)$,

ϕ derived by replacing the phrase “ y ” in $\gamma(y)$ with q

- ▶ **Only difference between ϕ and ψ :** $\gamma(y)$ instead of $\langle q \rangle$

- ▶ **But recall that** $q = \ulcorner \gamma(y) \urcorner$, i.e. $\langle q \rangle \equiv \gamma(y)$

- ▶ So, in fact, $\psi \equiv \phi$

- ▶ Hence ϕ states “ ϕ is not provable in PA1”

Note: the replacement of y with q in meta-language is encoded by $\text{sost}()$ in PA1

Subsection 3

Turing

Turing machines

- ▶ Turing Machine (TM): *computation model*
 - ▶ infinite tape with cells storing finite alphabet letters
 - ▶ head reads/writes/skips i -th cell, moves left/right
 - ▶ states=program (e.g. if s write 0, move left, change to state t)
 - ▶ initial tape content: input, final tape content: output
 - ▶ final state \perp : termination (*nontermination denoted \emptyset*)
 - ▶ can model PA1
- ▶ \exists universal TM (UTM) U s.t.
 - ▶ given the “program” of a TM T and an input x
 - ▶ U “simulates” T running on x
- ▶ \Rightarrow The basis of the modern computer
- ▶ TMs can be represented as sentences in PA1
see [this proof](#) (click here)
we'll see a similar proof while discussing Cook's theorem in Ch. 3

The halting problem

▶ **HALTING PROBLEM (HP):**

given TM M and input x , is $M(x) = \perp$?

i.e. *does a given TM terminate on its input?*

▶ **Turing's theorem: HP is undecidable**

TM's can be represented in PA1 \Rightarrow so can HP

▶ **HP is an undecidable sentence in PA1**

\Rightarrow **PA1 is undecidable**

Turing's theorem: Computable functions

- ▶ TM T on input x yielding output y : write $T(x) = y$
- ▶ If a TM T terminates on all input, $T(\cdot)$ is *computable*
a.k.a. "total computable"
- ▶ If a function is not computable, then it's *uncomputable*
- ▶ If T only terminates on some input, $T(\cdot)$ is *partial computable*
Recall $T(x) = \emptyset$ (undefined) if T does not terminate on input x
- ▶ Every total computable function is also (trivially) partial computable
- ▶ If a partial computable function is not total, then it is *uncomputable*

Turing's theorem: Proof

- ▶ Enumerate all TMs: $(M_i \mid i \in \mathbb{N})$
- ▶ Halting function $\text{halt}(i, \ell) = \begin{cases} 1 & \text{if } M_i(\ell) = \perp \\ 0 & \text{if } M_i(\ell) = \emptyset \end{cases}$
- ▶ Show $\text{halt} \neq F$ for any total computable $F(i, \ell)$:
 - ▶ define $G(i) = 0$ if $F(i, i) = 0$ or undefined (\emptyset) othw
 G is partial computable because F is computable
 - ▶ let M_j be the TM computing G
for any i , $M_j(i) = \perp$ iff $G(i) = 0$ (since $G(i)$ undefined othw)
 - ▶ consider $\text{halt}(j, j)$:
 - ▶ $\text{halt}(j, j) = 1 \rightarrow M_j(j) = \perp \rightarrow G(j) = 0 \rightarrow F(j, j) = 0$
 - ▶ $\text{halt}(j, j) = 0 \rightarrow M_j(j) = \emptyset \rightarrow G(j) = \emptyset \rightarrow F(j, j) \neq 0$
 - ▶ so $\text{halt}(j, j) \neq F(j, j)$ for all j
- ▶ \Rightarrow halt is not total computable
 - $\Rightarrow \exists$ inputs on which the TM for halt does not terminate
 - $\Rightarrow \nexists$ single terminating algorithm to solve all instances of HP

Subsection 4

Tarski

Example: Reals

- ▶ **Tarski's theorem:** Reals is complete
- ▶ **Algorithm:**
constructs solution sets (YES) or contradictions (NO)
⇒ provides proofs or contradictions for all sentences
- ▶ ⇒ Reals is complete **and also decidable**
(since every complete theory is decidable, see next slide)

Completeness \Rightarrow decidability

► Given $\phi \in \mathcal{F}$

$i = 0$

while 1 do

if **proof**($i, \lceil \phi \rceil$) **then**

 return **YES**

else if **proof**($i, \lceil \neg \phi \rceil$) **then**

 return **NO**

end if

$i = i + 1$

end while

► Since \mathcal{F} complete, algorithm terminates on all ϕ

Tarski's theorem

- ▶ Algorithm based on quantifier elimination
- ▶ *Feasible sets of polynomial systems $p(x) \leq 0$ have finitely many connected components*
- ▶ Each connected component recursively built of cylinders over points or intervals
extremities: pts., $\pm\infty$, algebraic curves at previous recursion levels
- ▶ In some sense, generalization of Reals in \mathbb{R}^1

Dense linear orders

Given a sentence ϕ in DLO (*similar to Reals in one dimension*)

- ▶ Reduce to DNF w/clauses $\exists x_i q_i(x)$ where $q_i = \bigwedge q_{ij}$
- ▶ Each q_{ij} has form $s = t$ or $s < t$ (s, t vars or consts)
 - ▶ s, t both constants:
 $s < t, s = t$ verified and replaced by 1 or 0
 - ▶ s, t the same variable x_i :
 $s < t$ replaced by 0, $s = t$ replaced by 1
 - ▶ if s is x_i and t is not:
 $s = t$ means “replace x_i by t ” (eliminate x_i)
 - ▶ remaining case:
 q_i conjunction of $s < x_i$ and $x_i < t$:
replace by $s < t$ (eliminate x_i)
- ▶ q_i no longer depends on x_i , rewrite $\exists x_i q_i$ as q_i
- ▶ Repeat over vars. x_i , obtain real intervals or contradictions

Quantifier elimination!

Subsection 5

Completeness and incompleteness

Decidability and completeness

- ▶ PA1 is incomplete and undecidable
- ▶ Reals is complete and decidable
- ▶ Are there FS \mathcal{F} that are:
 - ▶ incomplete and decidable?
 - ▶ complete and undecidable?
this case already discussed, answer is NO

Incomplete and decidable (trivial)

- ▶ **NoInference:**
Any FS with $< \infty$ axiom schemata and no inference rules
- ▶ Only possible proofs: **sequences of axioms**
- ▶ Only provable sentences: **axioms**
- ▶ For any other sentence f : **no proof of f or $\neg f$**
- ▶ **Trivial decision algorithm:**
given f , output **YES** if f is a finite axiom sequence,
NO otherwise
- ▶ **NoInference is incomplete and decidable**

Incomplete and decidable (nontrivial)

- ▶ ACF: Algebraically Closed Fields (e.g. \mathbb{C})
field axioms + “every polynomial splits” schema
- ▶ **Theorem:** ACF is incomplete
 - ▶ ACF_p : $\text{ACF} \wedge C_p \equiv [\sum_{j \leq p} 1 = 0]$ (with p prime)
 - ▶ **Claim:** $\forall p$ (prime) C_p independent of ACF
 - ▶ suppose proof of C_p or $\neg C_p$ possible for p
 - ▶ then either $\text{ACF} \wedge \neg C_p$ or $\text{ACF} \wedge C_p$ inconsistent
 - ▶ but \exists field of *any* prime characteristic p
 - ▶ $\text{ACF} \wedge C_p$ and $\text{ACF} \wedge \neg C_p$ consistent for all p
- ▶ **Theorem:** ACF is decidable

Decision algorithm $\mathcal{D}(\psi)$ for ACF:

- ▶ if $\psi \equiv C_p$ or $\neg C_p$ for some prime p , return NO
 - ▶ else run quantifier elimination on ψ'
 ψ' obtained by replacing $\sum_{j \leq p} 1$ by 0 whenever possible in ψ
- ▶ \Rightarrow ACF is incomplete and decidable

The two meanings of *completeness*

▶ WARNING!!!

“complete” is used in two different ways in logic

1. Gödel's 1st incompleteness theorem

FS \mathcal{F} complete₁ if ϕ or $\neg\phi$ provable $\forall\phi$

2. Gödel's completeness₂ theorem

- ▶ A : set of sentences in \mathcal{F}
- ▶ M a *model* of \mathcal{F} (domain of values for var symbols)
- ▶ A^M : each var in A replaced by corresp. value
- ▶ $\exists M$ s.t. A^M is true $\Rightarrow A$ consistent

partial converse: corollary of Gödel's completeness thm

- ▶ **Complete₂** FS: $\forall M (A^M) \Rightarrow \mathcal{F} \vdash A$
- ▶ *Gödel's completeness theorem:*
1st order logic is **complete₂**
- ▶ **Note the strong assumption “ $\forall M$ ”**

incompleteness theorem only considers $M = \mathbb{N}$

▶ *Pay attention when reading literature/websites*

Subsection 6

MP solvability

The issue

- ▶ Proved PA1 incomplete and undecidable
- ▶ Proved Reals complete and decidable
- ▶ But MP feasibility problems are *existential statements*

$$\exists x \text{ s.t. } g(x) \leq 0 ?$$

- ▶ PA1 and Reals also involve universal quantifiers
 \Rightarrow MP feasibility provides smaller theories
- ▶ For Reals, if larger theory complete and decidable, smaller theory also complete and decidable
- ▶ For PA1, larger theory incomplete and undecidable, but smaller theory might be complete or decidable!

Polynomial equations in integers

- ▶ Consider the feasibility-only MP

$$\min\{0 \mid \forall i \leq m \ g_i(x) = 0 \wedge x \in \mathbb{Z}^n\}$$

with $g_i(x)$ multivariate polynomials in x

- ▶ Rewrite as a *Diophantine equation* (DE):

$$\exists x \in \mathbb{Z}^n \quad \sum_{i \leq m} (g_i(x))^2 = 0 \quad (1)$$

- ▶ Can restrict to \mathbb{N} wlog, i.e. Eq. (1) \in PA1
write $x_i = x_i^+ - x_i^-$ where $x_i^+, x_i^- \in \mathbb{N}^n$
- ▶ Formulæ of PA1 are generally undecidable
but is the subclass (1) of PA1 decidable or not?

Hilbert's 10th problem

▶ Hilbert:

Given a Diophantine equation with any number of unknowns and with integer coefficients: devise a process which could determine by a finite number of operations whether the equation is solvable in integers

▶ Davis & Putnam: conjecture DEs are undecidable

- ▶ consider set \mathbb{RE} of *recursively enumerable* (r.e.) sets
- ▶ $R \subseteq \mathbb{N}$ is in \mathbb{RE} if \exists TM listing all and only elements in R
let $\text{TM} = \{T : \mathbb{N} \rightarrow \mathbb{N} \mid T \text{ is a TM}\};$
then $\forall R \in \mathbb{RE} \exists T \in \text{TM} (\text{ran } T = R)$
- ▶ some \mathbb{RE} sets are undecidable, e.g. $R = \{\ulcorner \alpha \urcorner \mid \text{PA1} \vdash \alpha\}$
r.e.: list all proofs; **undecidable:** by Turing's thm
“listing elements of set” different from “proving element in set”
- ▶ for each $R \in \mathbb{RE}$ show \exists polynomial $p(r, x)$ s.t.
$$r \in R \leftrightarrow \exists x \in \mathbb{N}^n p(r, x) = 0$$
- ▶ **if we can prove this, \exists undecidable DEs**
othw $\forall r \in \mathbb{N}$ decide if $r \in R$ by finding $x \in \mathbb{N}^n : p(r, x) = 0$
against undecidability of PA1

Proof strategy

- ▶ **Strategy:** “model” r.e. sets with polynomial equations in integers
- ▶ **D&P+Robinson:** universal quantifiers removed, but eqn system involves exponentials
- ▶ **Matiyasevich:** exploits exponential growth of Pell’s equation solutions to remove exponentials
- ▶ \Rightarrow DPRM theorem, implying DE undecidable
Negative answer to Hilbert’s 10th problem

Structure of the DPRM theorem

- ▶ Gödel's proof of his 1st incompleteness thm.

r.e. sets \equiv DEs with $< \infty \exists$ and bounded \forall quantifiers

- ▶ Davis' normal form

one bounded quantifier suffices: $\exists x_0 \forall a \leq x_0 \exists x p(a, x) = 0$

- ▶ (2 bnd qnt \equiv 1 bnd qnt on pairs) and induction

- ▶ Robinson's idea

get rid of bounded universal quant. by using exponent vars

- ▶ idea: $[\exists x_0 \forall a \leq x_0 \exists x p(a, x) = 0]$ “ \rightarrow ” $\left[\exists x \prod_{a \leq x_0} p(a, x) = 0 \right]$

- ▶ precise encoding needs variables in exponents

- ▶ Matiyasevic's contribution

express $c = b^a$ using polynomials

- ▶ use Pell's equation $x^2 - dy^2 = 1$

- ▶ solutions (x_n, y_n) satisfy $x_n + y_n \sqrt{d} = (x_1 + y_1 \sqrt{d})^n$

- ▶ $x_n = O(d^{n/2}) \Rightarrow$ can express exponentials with polynomials

MP is unsolvable

- ▶ $R \in \mathbb{RE} \Rightarrow \exists T \in \mathbb{TM}$ s.t. $\text{ran } T = R$ by defn, now prove converse
- ▶ **Lemma:** $\forall T \in \mathbb{TM} \text{ ran } T \in \mathbb{RE}$
 - ▶ **Pf:** Consider list of all TMs ($M_i \mid i \in \mathbb{N}$)
if $M_i(x) = \perp$ at t -th execution step, write $M_i^t(x) = \perp$
 - ▶ Yields all sets in $\mathbb{RE} = (R_i \mid i \in \mathbb{N})$ by dovetailing
 $\Rightarrow \forall k \in \mathbb{N}, t < k, i \leq t$ if $M_i^t(k-t) = \perp$ append $k-t$ to R_i
 $\Rightarrow R_i = \{k-t \mid \exists k \in \mathbb{N}, t < k : M_i^t(k-t) = \perp\}$ \square
- ▶ DPRM theorem: $\forall R \in \mathbb{RE}$, R represented by poly eqn
- ▶ By **lemma**, can choose UTM M_i with $\text{ran } M_i = R_i \in \mathbb{RE}$
 $\Rightarrow \exists$ Universal DE (UDE), say $U(r, x) = 0$
- ▶ UTM simulates HP algorithm but HP undecidable:
 $\exists r \forall x U(r, x) \neq 0$
- ▶ $\min\{0 \mid U(r, x) = 0 \wedge x \in \mathbb{N}^n\}$: **undecidable (feasibility) MP**
- ▶ $\min_{x \in \mathbb{N}^n} (U(r, x))^2$: **unsolvable (optimization) MP**

Common misconception

“Since \mathbb{N} is contained in \mathbb{R} , how is it possible that Reals is decidable but DE (= Reals \cap \mathbb{N} , right?) is not?”

After all, if a problem contains a hard subproblem, it's hard by inclusion, right?

- ▶ Can you express DE $p(x) = 0 \wedge x \in \mathbb{N}$ in Reals?
 - ▶ $p(x) = 0$ belongs to both DE and Reals, OK
 - ▶ “ $x \in \mathbb{N}$ ” in Reals?
 - \Leftarrow find poly $q(x)$ s.t. $\exists x q(x) = 0$ iff $x \in \mathbb{N}^n$
 - ▶ $q(x) = x(x-1)\cdots(x-a)$ only good for $\{0, 1, \dots, a\}$
 $q(x) = \prod_{i \in \omega} (x-i)$ is ∞ ly long, invalid
 - ▶ **IMPOSSIBLE!**
 - if it were possible, DE would be decidable, contradiction*
 - ▶ \Rightarrow Reals $\not\subseteq$ DE

MIQCP is undecidable

- ▶ [Jeroslow 1973]: MIQCP:

$$\left. \begin{array}{l} \min \\ \forall i \leq m \end{array} \right\} \left. \begin{array}{l} c^\top x \\ x^\top Q^i x + a_i^\top x + b_i \geq 0 \\ x \in \mathbb{Z}^n \end{array} \right\} \quad (\dagger)$$

is **undecidable**

Proof:

- ▶ Let $U(r, x) = 0$ be an UDE
- ▶ $P(r) \equiv \min\{u \mid (1-u)U(r, x) = 0 \wedge u \in \{0, 1\} \wedge x \in \mathbb{Z}^n\}$
 $P(r)$ describes an unsolvable problem
- ▶ Linearize every product $x_i x_j$ by y_{ij} and add $y_{ij} = x_i x_j$
until only degree 1 and 2 left
- ▶ Obtain instances of MIQCP (\dagger) for every r

Some MIQCQPs are decidable

- ▶ If each Q_i is diagonal PSD, **decidable** [Witzgall 1963]
-

- ▶ If x are bounded in $[x^L, x^U] \cap \mathbb{Z}^n$, **decidable**
can express $x \in \{[x^L], [x^L] + 1, \dots, [x^U]\}$ by polynomial

$$\forall i \leq m \quad \prod_{x_i^L \leq i \leq x_i^U} (x - i) = 0$$

turn into poly system in \mathbb{R} (in Reals, decidable)

- ▶ \Rightarrow **Bounded** (vars) easier than **unbounded** (for \mathbb{Z})
-

- ▶ [MIQP decision vers.] is **decidable**
$$\left. \begin{array}{l} x^\top Qx + c^\top x \leq \gamma \\ Ax \geq b \\ \forall j \in Z \quad x_j \in \mathbb{Z} \end{array} \right\} \quad (\text{in NP [Del Pia et al. 2014]})$$

NLP is undecidable

We can't represent unbounded subsets of \mathbb{N} by polynomials

But we can if we allow some transcendental functions

$$x \in \mathbb{Z} \iff \sin(\pi x) = 0$$

- ▶ Constrained NLP is undecidable:

$$\min\{0 \mid U(a, x) = 0 \wedge \forall j \leq n \sin(\pi x_j) = 0\}$$

- ▶ Even with just one nonlinear constraint:

$$\min\{0 \mid (U(a, x))^2 + \sum_{j \leq n} (\sin(\pi x_j))^2 = 0\}$$

- ▶ Unconstrained NLP is undecidable:

$$\min(U(a, x))^2 + \sum_{j \leq n} (\sin(\pi x_j))^2$$

- ▶ Box-constrained NLP is undecidable (*boundedness doesn't help*):

$$\min\{(U(a, \tan x_1, \dots, \tan x_n))^2 + \sum_{j \leq n} (\sin(\pi \tan x_j))^2 \mid -\frac{\pi}{2} \leq x \leq \frac{\pi}{2}\}$$

Some NLPs are decidable

- ▶ All polynomial NLPs are **decidable**

by decidability of Reals

- ▶ QUADRATIC PROGRAMMING (QP) is **decidable over \mathbb{Q}**

$$\left. \begin{array}{l} \min \quad x^\top Qx + c^\top x \\ \quad Ax \geq b \end{array} \right\} \quad (P)$$

- ▶ *Bricks of the proof*

- ▶ if Q is PSD, $[P] \in \mathbb{Q}$

1. *remove inactive constr., active are eqn, use to replace vars*
2. *work out KKT conditions, they are linear in rational coefficients*
3. \Rightarrow *solution is rational*

- ▶ \exists polytime IPM for solving P [Renegar&Shub 1992]

- ▶ *unbounded case treated in [Vavasis 1990]*

- ▶ \Rightarrow [QP decision version] is in **NP**

\Rightarrow **QP is decidable over \mathbb{Q}**

Rationals

- ▶ [Robinson 1949]:
RT (1st ord. theory over \mathbb{Q}) is undecidable
- ▶ [Pheidas 2000]: *existential* theory of \mathbb{Q} (ERT) is open
can we decide whether $p(x) = 0$ has solutions in \mathbb{Q} ? Boh!
- ▶ [Matyiashevich 1993]:
 - ▶ equivalence between DEH and ERT
 - ▶ DEH = [DE restricted to homogeneous polynomials]
 - ▶ *but we don't know whether DEH is decidable*

Note that Diophantus solved DE in positive rationals

Outline

Introduction

- MP language
- Solvers
- MP systematics
- Some applications

Decidability

- Formal systems
- Gödel
- Turing
- Tarski
- Completeness and incompleteness
- MP solvability

Efficiency and Hardness

- Some combinatorial problems in NP
- NP-hardness
- Complexity of solving MP formulations

Distance Geometry

- The universal isometric embedding
- Dimension reduction
- Dealing with incomplete metrics
- The Isomap heuristic
- Distance geometry problem
- Distance geometry in MP
- DGP cones
- Barvinok's Naive Algorithm
- Isomap revisited

Summary

Random projections in LP

- Random projection theory
- Projecting LP feasibility
- Projecting LP optimality
- Solution retrieval
- Application to quantile regression

Sparsity and ℓ_1 minimization

- Motivation
- Basis pursuit
- Theoretical results
- Application to noisy channel encoding
- Improvements

Kissing Number Problem

- Lower bounds
- Upper bounds from SDP?
- Gregory's upper bound
- Delsarte's upper bound
- Pfender's upper bound

Clustering in Natural Language

- Clustering on graphs
- Clustering in Euclidean spaces
- Distance instability
- MP formulations
- Random projections again

Worst-case algorithmic complexity

- ▶ Computational complexity theory:
worst-case time/space taken by an algorithm to complete
- ▶ Given an algorithm \mathcal{A}
 - ▶ e.g. to determine whether a graph $G = (V, E)$ is connected or not
 - ▶ input: G ; size of input: $\nu = |V| + |E|$
- ▶ How does $\text{cpu}(\mathcal{A})$ vary with ν ?
 - ▶ $\text{cpu}(\mathcal{A}) = O(\log \nu)$: logarithmic (sublinear)
 - ▶ $\text{cpu}(\mathcal{A}) = O(\log^k \nu)$ for fixed k : polylogarithmic
 - ▶ $\text{cpu}(\mathcal{A}) = O(\nu)$: linear
 - ▶ $\text{cpu}(\mathcal{A}) = O(\nu^2)$: quadratic
 - ▶ $\text{cpu}(\mathcal{A}) = O(\nu^k)$ for fixed k : polytime
 - ▶ $\text{cpu}(\mathcal{A}) = O(2^\nu)$: exponential
- ▶ polytime \leftrightarrow efficient
- ▶ exponential \leftrightarrow inefficient

The “ $O(\cdot)$ ” calculus

$$\forall f, g : \mathbb{N} \rightarrow \mathbb{N} \quad f <_O g \quad \leftrightarrow \quad \exists n \in \mathbb{N} \forall \nu > n (f(\nu) < g(\nu))$$

$$\forall g : \mathbb{N} \rightarrow \mathbb{N} \quad O(g) = \{f : \mathbb{N} \rightarrow \mathbb{N} \mid \exists C \in \mathbb{N} (f <_O Cg)\}$$

$$\forall f, g : \mathbb{N} \rightarrow \mathbb{N} \quad O(f) < O(g) \quad \leftrightarrow \quad f \in O(g) \wedge g \notin O(f)$$

Are polytime algorithms “efficient”?

- ▶ Why are polynomials special?
- ▶ Many different variants of Turing Machines (TM)
more tapes, more heads, ...
- ▶ Polytime is *invariant* to all definitions of TM
e.g. TM with ∞ ly many tapes: simulate with a single tape running along diagonals, similarly to dovetailing
- ▶ In practice, $O(\nu)$ - $O(\nu^3)$ is an acceptable range covering most practically useful efficient algorithms
- ▶ Many exponential algorithms are also usable in practice for limited sizes
- ▶ Sublinear algorithms aren't allowed to read their whole input!

Instances and problems

- ▶ An input to an algorithm \mathcal{A} : *instance*
- ▶ Collection of all inputs for \mathcal{A} : *problem*
in general, a problem P is an infinite set of instances
- ▶ \mathcal{A} solves P if \mathcal{A} solves **every instance** of P
 - ▶ There are problems which no algorithm can solve
 - ▶ A problem can be solved by different algorithms
- ▶ Given P find complexity of *best alg.* \mathcal{A} solving P

$$\min_{<0} \{ \text{cpu}(\mathcal{A}) \mid \mathcal{A} \text{ solves } P \}$$

- ▶ We (generally) don't know how to search over all algs for P
sometimes we can find complexity bounds

Complexity classes: \mathbf{P} , \mathbf{NP}

- ▶ Focus on *decision problems*
- ▶ If \exists polytime algorithm for P , then $P \in \boxed{\mathbf{P}}$
- ▶ If there is a polytime checkable *certificate* for all YES instances of P , then $P \in \boxed{\mathbf{NP}}$
e.g. SHORTEST s — t PATH WITH $\leq K$ EDGES in a graph G ; path itself is a certificate: it can be checked whether it has fewer than K edges in time proportional to $K \leq |G|$
- ▶ We know $\mathbf{P} \subseteq \mathbf{NP}$:
polytime alg for P provides polysized *trace* certifying YES
algorithmic trace: list of instructions with loops unfolded
- ▶ No-one knows whether $\mathbf{P} = \mathbf{NP}$: **we think not**
- ▶ Examples of \mathbf{NP} problems unlikely to have polytime alg:
k-CLIQUE, SUBSET-SUM, KNAPSACK, HAMILTONIAN CYCLE, SAT

Equivalent definition of NP

- ▶ **NP**: problems solved by *nondeterministic* polytime TM

nondeterministic: follow all paths concurrently, stop at first YES

- ▶ **Equivalence with previous definition**
 - ▶ (\Rightarrow) Assume \exists polysized certificate for every YES instance. Nondeterministic polytime algorithm: concurrently explore all possible polysized certificates, call verification oracle for each, determine YES/NO.
 - ▶ (\Leftarrow) Run nondeterministic polytime algorithm: trace will look like a tree (branchings at tests, loops unrolled) with polytime depth. If YES there will be a terminating polysized sequence of steps from start to termination, serving as a polysized certificate

Subsection 1

Some combinatorial problems in **NP**

k -STABLE

- ▶ Instance: $(G = (V, E), k)$
- ▶ Problem: determine if G has a *stable set* of size k
 - ▶ A subset $U \subseteq V$ is *stable* if $G[U]$ is *empty*
 - ▶ For $G = (V, E)$ and $U \subseteq V$, the *subgraph of G induced by U* is
$$G[U] = (U, \{\{u, v\} \in E \mid u, v \in U\})$$
 - ▶ $G = (V, E)$ is *empty* if $E = \emptyset$

-
- ▶ 1-STABLE? YES (every graph with ≥ 1 vertices is YES)
 - ▶ 2-STABLE? YES (every non-complete graph is YES)
 - ▶ 3-STABLE? NO

Variables? Objective? Constraints?

MP formulation for SAT

Variables? Objective? Constraints?

Algorithm $\hat{\rho}$ to generate MP from given SAT sentence $\bigwedge_{i \leq m} \bigvee_{j \in C_i} \ell_j$:

MP formulation for SAT

Variables? Objective? Constraints?

Algorithm $\hat{\rho}$ to generate MP from given SAT sentence $\bigwedge_{i \leq m} \bigvee_{j \in C_i} \ell_j$:

- ▶ Literals $\ell_j \in \{x_j, \bar{x}_j\}$: *decision variables in $\{0, 1\}$*

$$\hat{\rho}(\ell_j) \longmapsto \begin{cases} x_j & \text{if } \ell_j \equiv x_j \\ 1 - x_j & \text{if } \ell_j \equiv \bar{x}_j \end{cases}$$

- ▶ Clauses $\Gamma_i \equiv \bigvee_{j \in C_i} \ell_j$: *constraints*

$$\hat{\rho}(\Gamma_i) \longmapsto \sum_{j \in C_i} \hat{\rho}(\ell_j) \geq 1$$

- ▶ **Conjunction:** *feasibility-only ILP*

$$\hat{\rho}\left(\bigwedge_i \Gamma_i\right) \longmapsto \forall i \leq m \quad \hat{\rho}(\Gamma_i)$$

MP formulation for SAT

- ▶ **Prop.:** SAT instance q is YES iff ILP instance $\hat{\rho}(q)$ is YES
- ▶ *Proof:* Let $L = (\ell'_1, \dots, \ell'_n)$ be a solution of SAT. Then $x^* = (x_1^*, \dots, x_n^*)$ where $x_j^* = 1$ iff $\ell'_j = x_j = \text{true}$ and $x_j^* = 0$ iff $\ell'_j = \bar{x}_j = \text{true}$ is a feasible solution of ILP (satisfies each clause constraint by definition of $\hat{\rho}$).
Conversely: if x solves ILP, then form solution L of SAT by mapping $x_j^* = 1$ to true and $x_j^* = 0$ to false, result follows again by defn of $\hat{\rho}$.
- ▶ **Algorithm $\hat{\rho}$** is called a *reduction* from SAT to ILP
reductions from Q to P model Q in terms of P

AMPL code for SAT?

Using $\hat{\rho}$ we can only obtain flat formulations

Example: file `sat.run` (flat formulation) for instance
 $(x_1 \vee \bar{x}_2 \vee x_3) \wedge (\bar{x}_1 \vee x_2)$

```
# sat.run
var x{1..3} binary;
subject to con1: x[1] + (1-x[2]) + x[3] >= 1;
subject to con2: (1-x[1]) + x[2] >= 1;
option solver cplex;
solve;
display x, solve_result;
```

Subsection 2

NP-hardness

NP-Hardness

- ▶ Do *hard* problems exist? Depends on $\mathbf{P} \neq \mathbf{NP}$
- ▶ Next best thing: define *hardest problem in NP*
- ▶ **Defn.:** Problem P is **NP-hard** if $\forall Q \in \mathbf{NP} \exists$ polytime alg. ρ_Q :

$q \in Q \mapsto \rho_Q(q) \in P$ with q YES iff $\rho_Q(q)$ YES

 $\rho_Q : Q \rightarrow P$ is called a *polynomial reduction* from Q to P
- ▶ **Prop.:** P is hardest for **NP**
 1. run best algorithm for P on $\rho_Q(q)$
get answer $\alpha \in \{\text{YES}, \text{NO}\}$
 2. return α as answer for q
 3. **so Q no harder than P**
since solved Q with alg for P + polytime taken by $\rho_Q(q)$
 4. holds $\forall Q \in \mathbf{NP} \Rightarrow$ nothing in **NP** harder than P
- ▶ If P is in **NP** and is **NP-hard**, it is called **NP-complete**
- ▶ *Reduction:* model Q using language of P
- ▶ Thm. [Cook 1971]: everything in **NP** reduces to SAT

Cook's theorem

Theorem 1: If a set S of strings is accepted by some nondeterministic Turing machine within polynomial time, then S is P-reducible to {DNF tautologies}.

TM dynamics modelled with Boolean vars

Proposition symbols:

$P_{s,t}^i$: for $1 \leq i \leq \ell$, $1 \leq s, t \leq T$.

$P_{s,t}^i$ is true iff tape square number s at step t contains the symbol σ_i .

Q_t^i for $1 \leq i \leq r$, $1 \leq t \leq T$. Q_t^i is true iff at step t the machine is in state q_i .

$S_{s,t}$ for $1 \leq s, t \leq T$ is true iff at time t square number s is scanned by the tape head.

Definition of TM dynamics in CNF

B_t asserts that at time t one and only one square is scanned:

$$B_t = (S_{1,t} \vee S_{2,t} \vee \dots \vee S_{T,t}) \ \&$$

$$[\ \&_{1 \leq i < j \leq T} (\neg S_{i,t} \vee \neg S_{j,t})]$$

$G_{i,j}^t$ asserts that if at time t the machine is in state q_i scanning symbol σ_j , then at time $t+1$ the machine is in state q_k , where q_k is the state given by the transition function for M .

$$G_{i,j}^t = \bigwedge_{s=1}^T (\neg Q_t^i \vee \neg S_{s,t} \vee \neg P_{s,t}^j \vee Q_{t+1}^k)$$

Description of a dynamical system using a declarative programming language (SAT) — what MP is all about!

The MP version of Cook's theorem

Thm.

Any problem P in **NP** can be polynomially reduced to a MILP

Proof

Since $P \in \mathbf{NP}$, every YES instance $\pi \in P$ must have a polynomial-time (say $p^P(|\pi|)$) verifiable certificate c_π (wlog assume it is a $\{0, 1\}$ string), with length bounded by a polynomial (say $q^P(|\pi|)$). This means that a deterministic TM M_P verifying c_π will reach termination in polytime $p^P(\pi)$. Let κ be such that $p^P, q^P \in O(|\pi|^\kappa)$. We define a MILP on binary variables holding the content of the tape of M_P as it changes according to the transition function of M_P , such that the tape contains: (i) “NO” in the first cell, and π in the subsequent $|\pi|$ cells, at the initial step $k = 0$; (ii) “YES” in the first cell at the final step $k = |\pi|^\kappa$. Then the MILP is feasible iff π is a YES instance of P . This provides a polytime reduction from P to MILP.

Cook's theorem: sets and params

- ▶ Model a deterministic TM dynamics using MILP
- ▶ M_P is a 5-tuple $(Q, \Sigma, s, F, \delta)$:
states, alphabet, initial, final, transition
- ▶ Transition function $\delta : Q \setminus F \times \Sigma \rightarrow Q \times \Sigma \times \{-1, 1\}$
 δ : state ℓ , symbol $j \mapsto$ state ℓ' , symbol j' , direction d
- ▶ M_P polytime: terminates in $|\pi|n^\kappa$
- ▶ *Index sets:*
states Q , characters Σ , tape cells I , steps K
- ▶ *Parameters:*
initial tape string (NO, π)
YES written in cell 1 when M_P in final state

Cook's theorem: decision vars

- ▶ $\forall i \in I, j \in \Sigma, k \in K$
 $t_{ijk} = 1$ iff tape cell i contains symbol j at step k
- ▶ $\forall i \in I, k \in K$
 $h_{ik} = 1$ iff head is at tape cell i at step k
- ▶ $\forall \ell \in Q, k \in K$
 $q_{\ell k} = 1$ iff M_P is in state ℓ at step k

Cook's theorem: constraints (informal)

1. *Initialization:*

- 1.1 initial string (NO, π) on tape at step $k = 0$
- 1.2 M_P in initial state s at step $k = 0$
- 1.3 initial head position on cell $i = 0$ at $k = 0$

2. *Execution:*

- 2.1 $\forall i, k$: cell i has exactly one symbol j at step k
- 2.2 $\forall k$: M_P is in exactly one state ℓ
- 2.3 $\forall k$: tape head M_P is at exactly one cell i
- 2.4 $\forall i, k$: if cell i changes symbol between steps k and $k + 1$, head must be on cell i at step k
- 2.5 $\forall k, i, j$: cell i and symbol j in state k lead to cells, symbol and states given by transition function δ

3. *Termination:*

- 3.1 M_P terminates at step $k \leq n^k$ w/YES written in cell 1

Cook's theorem: constraints

1. Initialization:

$$1.1 \quad (t_{1, \text{NO}, 0} = 1) \wedge (\forall i > 1 \quad t_{i, \pi_i, 0} = 1)$$

$$1.2 \quad q_{s, 0} = 1$$

$$1.3 \quad h_{0, 0} = 1$$

2. Execution:

$$2.1 \quad \forall i, k \quad \sum_j t_{ijk} = 1$$

$$2.2 \quad \forall k \quad \sum_\ell q_{\ell k} = 1$$

$$2.3 \quad \forall k \quad \sum_i h_{ik} = 1$$

$$2.4 \quad \forall i, j \neq j', k < n^\kappa \quad t_{ijk} t_{i, j', k+1} \leq h_{ik}$$

$$2.5 \quad \forall i, \ell, \ell', j, j', k, d \text{ s.t. } (\ell', j', d) = \delta(\ell, j)$$

$$h_{ik} q_{\ell k} t_{ijk} = h_{i+d, k+1} q_{\ell', k+1} t_{i, j', k+1}$$

3. Termination:

$$3.1 \quad (t_{1, \text{YES}, n^\kappa} = 1) \wedge \left(\sum_{f \in F, k} q_{fk} = 1 \right)$$

Cook's theorem: linearization

- ▶ MP in previous slide: **MINLP** not MILP
- ▶ Fortet's inequalities for products of binary vars:
For $x, y \in \{0, 1\}$ and $z \in [0, 1]$
 $z = xy \Leftrightarrow z \leq x \wedge z \leq y \wedge z \geq x + y - 1$

- ▶ MILP is feasibility only
- ▶ MILP has polynomial size
- ▶ \Rightarrow **MILP is NP-hard**

Reduction graph

After Cook's theorem

To prove **NP-hardness** of a new problem P , pick a known **NP-hard** problem Q that “looks similar enough” to P and find a polynomial reduction ρ_Q from Q to P [Karp 1972]

Why it works: suppose P easier than Q , solve Q by calling $\text{Alg}_P \circ \rho_Q$, conclude Q as easy as P , contradiction since Q hardest in **NP**

Example of polynomial reduction

- ▶ STABLE: given $G = (V, E)$ and $k \in \mathbb{N}$, does it contain a stable set of size k ?
- ▶ Assuming k -CLIQUE is **NP-complete**, reduce from it
 - ▶ Given instance (G, k) of CLIQUE consider the *complement graph* (computable in polytime)

$$\bar{G} = (V, \bar{E} = \{\{i, j\} \mid i, j \in V \wedge \{i, j\} \notin E\})$$

- ▶ **Prop.:** G has clique of size k iff \bar{G} has stable set of size k
 - ▶ $\rho(G) = \bar{G}$ a polynomial reduction CLIQUE \rightarrow STABLE
- ▶ \Rightarrow STABLE is **NP-hard**
- ▶ STABLE is also in **NP**
 - $U \subseteq V$ is a stable set iff $E(G[U]) = \emptyset$ (polytime verification)
- ▶ \Rightarrow STABLE is **NP-complete**

Subsection 3

Complexity of solving MP formulations

LP is in P

- ▶ Khachian's algorithm (Ellipsoid method)
- ▶ Karmarkar's algorithm
- ▶ IPM with crossover
 - IPM: penalize $x \geq 0$ by $-\beta \log(x)$, polysized sequence of subproblems*
 - crossover: polytime number of simplex pivots get to opt*
- ▶ No known pivot rule makes simplex alg. polytime!
 - greedy pivot has exponential complexity on Klee-Minty cube*

(Recall) MILP is **NP**-hard

- ▶ SAT **NP**-hard by Cook's theorem, **reduce from SAT**

$$\bigwedge_{i \leq m} \bigvee_{j \in C_i} \ell_j$$

where ℓ_j is either x_j or $\bar{x}_j \equiv \neg x_j$

- ▶ Polynomial reduction $\hat{\rho}$

SAT	x_j	\bar{x}_j	\vee	\wedge
MILP	x_j	$1 - x_j$	$+$	≥ 1

- ▶ E.g. $\hat{\rho}$ maps $(x_1 \vee x_2) \wedge (\bar{x}_2 \vee x_3)$ to

$$\min\{0 \mid x_1 + x_2 \geq 1 \wedge x_3 - x_2 \geq 0 \wedge x \in \{0, 1\}^3\}$$

- ▶ SAT is YES iff MILP is feasible

Complexity of Quadratic Programming (QP)

$$\min \left. \begin{array}{l} x^\top Qx + c^\top x \\ Ax \geq b \end{array} \right\}$$

- ▶ Quadratic obj, linear constra, continuous vars
- ▶ Many applications (e.g. portfolio selection)
- ▶ If Q has at least one negative eigenvalue, **NP-hard**
- ▶ Decision problem: “is the min. obj. fun. value ≤ 0 ?”
- ▶ If Q PSD then objective is convex, problem is in **P**
KKT conditions become linear system, data in $\mathbb{Q} \Rightarrow$ soln in \mathbb{Q}

QP is NP-hard

- ▶ By reduction from SAT, let σ be an instance of SAT
- ▶ $\hat{\rho}(\sigma, x) \geq 1$: linear constraints of (SAT \rightarrow MILP) reduction
- ▶ Consider QP subclass

$$\left. \begin{array}{l} \min \quad f(x) = \sum_{j \leq n} x_j(1 - x_j) \\ \hat{\rho}(\sigma, x) \geq 1 \\ 0 \leq x \leq 1 \end{array} \right\} \quad (\dagger)$$

- ▶ **Claim:** σ is YES iff $\text{val}(\dagger) \equiv \text{opt. obj. fun. val. of } (\dagger) = 0$
- ▶ *Proof:*
 - ▶ assume σ YES with soln. x^* , then $x^* \in \{0, 1\}^n$, hence $f(x^*) = 0$, since $f(x) \geq 0$ for all x , $\text{val}(\dagger) = 0$
 - ▶ assume σ NO, suppose $\text{val}(\dagger) = 0$, then (\dagger) feasible with soln. x' , since $f(x') = 0$ then $x' \in \{0, 1\}$, feasible in SAT hence σ is YES, contradiction

Box-constrained QP is **NP**-hard

$$\min_{x \in [x^L, x^U]} \left. \begin{array}{l} x^\top Qx + c^\top x \end{array} \right\}$$

- ▶ Add surplus vars v to SAT \rightarrow MILP constraints:

$$\hat{\rho}(\sigma, x) - 1 - v = 0$$

(denote by $\forall i \leq m (a_i^\top x - b_i - v_i = 0)$)

- ▶ Consider special QP subclass

$$\min \left. \begin{array}{l} \sum_{j \leq n} x_j(1 - x_j) + \sum_{i \leq m} (a_i^\top x - b_i - v_i)^2 \\ 0 \leq x \leq 1, v \geq 0 \end{array} \right\}$$

- ▶ Issue: v not bounded above
- ▶ Reduce from 3SAT, get ≤ 3 literals per clause
 \Rightarrow can consider $0 \leq v \leq 2$

cQKP is NP-hard

- ▶ CONTINUOUS QUADRATIC KNAPSACK PROBLEM (cQKP)

$$\left. \begin{array}{l} \min f(x) = x^\top Qx + c^\top x \\ \sum_{j \leq n} a_j x_j = \gamma \\ x \in [0, 1]^n, \end{array} \right\}$$

- ▶ Reduction from SUBSET-SUM

given list $a \in \mathbb{Q}^n$ and γ , is there $J \subseteq \{1, \dots, n\}$ s.t. $\sum_{j \in J} a_j = \gamma$?

reduce to cQKP subclass with $f(x) = \sum_j x_j(1 - x_j)$

- ▶ σ is a YES instance of SUBSET-SUM

- ▶ let $x_j^* = 1$ iff $j \in J$, $x_j^* = 0$ otherwise

- ▶ feasible by construction

- ▶ f is non-negative on $[0, 1]^n$ and $f(x^*) = 0$: optimum

- ▶ σ is a NO instance of SUBSET-SUM

- ▶ suppose $\text{opt}(\text{cQKP}) = x^*$ with $f(x^*) = 0$

- ▶ then $x^* \in \{0, 1\}^n$ because $f(x^*) = 0$

- ▶ feasibility of $x^* \Rightarrow J = \text{supp}(x^*)$ solves σ , contradiction $\Rightarrow f(x^*) > 0$

QP on a simplex is **NP**-hard

$$\left. \begin{array}{l} \min \quad f(x) = x^\top Qx + c^\top x \\ \sum_{j \leq n} x_j = 1 \\ \forall j \leq n \quad x_j \geq 0 \end{array} \right\}$$

- Reduce MAX CLIQUE to subclass with $f(x) = - \sum_{\{i,j\} \in E} x_i x_j$

Motzkin-Straus Formulation (MSF):

$$\max \left\{ \sum_{\{i,j\} \in E} x_i x_j \mid \sum_{j \in V} x_j = 1 \wedge x \geq 0 \right\}$$

- Theorem [Motzkin& Straus 1964]

Let C be max. clique of instance $G = (V, E) \in \text{MAX CLIQUE}$, and $\omega(G) = |C|$

$\exists x^* \in \text{opt}(\text{MSF})$ with $f^* = f(x^*) = \frac{1}{2} - \frac{1}{2\omega(G)}$

$$\forall j \in V \quad x_j^* = \begin{cases} \frac{1}{\omega(G)} & \text{if } j \in C \\ 0 & \text{otherwise} \end{cases}$$

Proof of the Motzkin-Straus theorem

$$x^* \in \arg\left(\max_{\substack{\sum_j x_j = 1 \\ x \geq 0}} \sum_{ij \in E} x_i x_j\right) \text{ s.t. } |C = \{j \in V \mid x_j^* > 0\}| \text{ smallest } (\dagger)$$

1. C is a clique

- ▶ Suppose $1, 2 \in C$ but $\{1, 2\} \notin E$, then $x_1^*, x_2^* > 0$, can perturb x^* by $\epsilon \in [-x_1^*, x_2^*]$, get $x^\epsilon = (x_1^* + \epsilon, x_2^* - \epsilon, x_3^*, x_4^*, \dots)$, feasible w.r.t. simplex and bound constraints
- ▶ $\{1, 2\} \notin E \Rightarrow x_1 x_2$ does not appear in $f(x) \Rightarrow f(x^\epsilon)$ depends at worst linearly on ϵ ; by local optimality of x^* , f achieves max for $\epsilon = 0$, in interior of its range $\Rightarrow f(x^\epsilon)$ constant w.r.t. ϵ . Hence $f(x^\epsilon)$ is globally optimal for all ϵ
- ▶ setting $\epsilon = -x_1^*$ or $\epsilon = x_2^*$ yields global optima with more zero components than x^* , against assumption (\dagger) , hence $\{1, 2\} \in E[C]$; by relabeling C is a clique

Proof of the Motzkin-Straus theorem

$x^* \in \arg(\max_{\substack{\sum_j x_j = 1 \\ x \geq 0}} \sum_{ij \in E} x_i x_j)$ s.t. $|C| = \{j \in V \mid x_j^* > 0\}$ is smallest

2. $|C| = \omega(G)$

▶ square the simplex constraint $\sum_j x_j = 1$, get

$$\psi(x) \equiv \sum_{j \in V} x_j^2 + 2 \sum_{i < j \in V} x_i x_j = 1$$

▶ by construction $x_j^* = 0$ for $j \notin C \Rightarrow \sum_{i < j \in C} x_i^* x_j^* = \sum_{ij \in E} x_i^* x_j^* \Rightarrow$

$$\psi(x^*) = \sum_{j \in C} (x_j^*)^2 + 2 \sum_{i < j \in C} x_i^* x_j^* = \sum_{j \in C} (x_j^*)^2 + 2f(x^*) = 1$$

▶ $\psi(x) = 1$ for all feasible x , so $f(x)$ achieves maximum when $\sum_{j \in C} (x_j^*)^2$ is minimum, i.e. $x_j^* = \frac{1}{|C|}$ for all $j \in C$ (since $\sum_j x_j^* = 1$)

▶ again by simplex constraint

$$2f(x^*) = 1 - \sum_{j \in C} (x_j^*)^2 = 1 - |C| \frac{1}{|C|^2} = 1 - \frac{1}{|C|} \leq 1 - \frac{1}{\omega(G)}$$

so $f(x^*)$ attains $\max \left(\frac{1}{2} - \frac{1}{2|C|} \right)$ when $|C| = \omega(G) \Rightarrow \forall j \in C \ x_j = \frac{1}{\omega(G)}$

Copositive programming

- ▶ STQP: $\min x^\top Qx : \sum_j x_j = 1 \wedge x \geq 0$

NP-hard by Motzkin-Straus

- ▶ **Linearize:** $X = xx^\top$

replace $x_i x_j$ by X_{ij} and add constraints $X_{ij} = x_i x_j$

- ▶ Define $A \bullet B = \text{tr}(A^\top B) = \sum_{i,j} A_{ij} B_{ij}$

write StQP (linearized) objective as $\min Q \bullet X$

- ▶ Let $C = \{X \mid X = xx^\top \wedge x \geq 0\}$, $\bar{C} = \text{conv}(C)$

- ▶ $\sum_j x_j = 1 \Leftrightarrow (\sum_j x_j)^2 = 1^2 \Leftrightarrow \mathbf{1} \bullet X = 1$

- ▶ STQP $\equiv \min Q \bullet X : \mathbf{1} \bullet X = 1 \wedge X \in C$

linear obj. \Rightarrow optima attained at extrema of feas. set

\Rightarrow can replace C by its convex hull \bar{C}

\bar{C} is a completely positive cone

- ▶ Dual $\equiv \max y : Q - y\mathbf{1} \in \bar{C}^* = \{A \mid \forall x \geq 0 (x^\top Ax \geq 0)\}$

\bar{C}^* is a copositive cone

- ▶ \Rightarrow **Pair of NP-hard cNLPs!**

An exercise and a project idea

You, a private investment banker, are seeing a customer. She tells you “I have 3,450,000\$ I don’t need in the next three years. Invest them in low-risk assets so I get at least 2.5% return per year.”

Model the problem of determining the required portfolio. Missing data are part of the fun (and of real life).

[What are the decision variables, objective, constraints? What data are missing?]

Project idea 1: Consider the MILP formulation for MAX CLIQUE and the Motzkin-Straus formulation. Can the latter have multiple global optima? If so, do they all characterize a maximum clique? What do local optima characterize? Pursue a computational study to answer these questions, then check [Gibbons et al., *Mathematics of Operations Research*, **22**:754-768, 1997] and [Pelillo & Jagota, *J. Artif. Neural Networks*, **2**:411-420, 1995]

Outline

Introduction

- MP language
- Solvers
- MP systematics
- Some applications

Decidability

- Formal systems
- Gödel
- Turing
- Tarski
- Completeness and incompleteness
- MP solvability

Efficiency and Hardness

- Some combinatorial problems in NP
- NP-hardness
- Complexity of solving MP formulations

Distance Geometry

- The universal isometric embedding
- Dimension reduction
- Dealing with incomplete metrics
- The Isomap heuristic
- Distance geometry problem
- Distance geometry in MP
- DGP cones
- Barvinok's Naive Algorithm
- Isomap revisited

Summary

Random projections in LP

- Random projection theory
- Projecting LP feasibility
- Projecting LP optimality
- Solution retrieval
- Application to quantile regression

Sparsity and ℓ_1 minimization

- Motivation
- Basis pursuit
- Theoretical results
- Application to noisy channel encoding
- Improvements

Kissing Number Problem

- Lower bounds
- Upper bounds from SDP?
- Gregory's upper bound
- Delsarte's upper bound
- Pfender's upper bound

Clustering in Natural Language

- Clustering on graphs
- Clustering in Euclidean spaces
- Distance instability
- MP formulations
- Random projections again

A gem in Distance Geometry

- ▶ *Heron's theorem*
- ▶ Heron lived around year 0
- ▶ Hung out at Alexandria's library

$$A = \sqrt{s(s-a)(s-b)(s-c)}$$

- ▶ A = area of triangle
- ▶ $s = \frac{1}{2}(a + b + c)$

Useful to measure areas of agricultural land

Heron's theorem: *Proof* [M. Edwards, high school student, 2007]

$$\mathbf{A.} \quad 2\alpha + 2\beta + 2\gamma = 2\pi \Rightarrow \alpha + \beta + \gamma = \pi$$

$$r + ix = ue^{i\alpha}$$

$$r + iy = ve^{i\beta}$$

$$r + iz = we^{i\gamma}$$

$$\Rightarrow (r + ix)(r + iy)(r + iz) = (uvw)e^{i(\alpha + \beta + \gamma)} = uvwe^{i\pi} = -uvw \in \mathbb{R}$$

$$\Rightarrow \operatorname{Im}((r + ix)(r + iy)(r + iz)) = 0$$

$$\Rightarrow r^2(x + y + z) = xyz \Rightarrow r = \sqrt{\frac{xyz}{x + y + z}}$$

$$\mathbf{B.} \quad s = \frac{1}{2}(a + b + c) = \frac{1}{2}(2x + 2y + 2z) = x + y + z$$

$$s - a = x + y + z - y - z = x$$

$$s - b = x + y + z - x - z = y$$

$$s - c = x + y + z - x - y = z$$

$$\Rightarrow \mathcal{A} = \frac{1}{2}(ra + rb + rc) = r \frac{a + b + c}{2} = rs = \sqrt{s(s - a)(s - b)(s - c)}$$

Subsection 1

The universal isometric embedding

Representing metric spaces in \mathbb{R}^n

- ▶ Given metric space (X, d) with dist. matrix (DM) $D = (d_{ij})$, embed X in some \mathbb{R}^K so it has the same DM
- ▶ Consider i -th row $x_i = (d_{i1}, \dots, d_{in})$ of D
- ▶ Embed $i \in X$ by vector $U^D(i) = x_i \in \mathbb{R}^n$
define $U^D : \{1, \dots, n\} \rightarrow \mathbb{R}^n$ s.t. $U^D(i) = x_i$
- ▶ **Thm.:** (U^D, ℓ_∞) is a metric space with DM D
i.e. $\forall i, j \leq n \ \|x_i - x_j\|_\infty = d_{ij}$
- ▶ U^D is called Universal Isometric Embedding (UIE)
- ▶ Practical issue: *embedding is high-dimensional (\mathbb{R}^n)*

[Kuratowski 1935]

Proof

- ▶ Consider $i, j \in X$ with distance $d(i, j) = d_{ij}$
- ▶ Then

$$\|x_i - x_j\|_\infty = \max_{k \leq n} |d_{ik} - d_{jk}| \leq \max_{k \leq n} |d_{ij}| = d_{ij}$$

ineq. \leq above from triangular inequalities in metric space:

$$\begin{aligned} \forall k \quad & d_{ik} \leq d_{ij} + d_{jk} \quad \wedge \quad d_{jk} \leq d_{ij} + d_{ik} \\ \Rightarrow & d_{ik} - d_{jk} \leq d_{ij} \quad \wedge \quad d_{jk} - d_{ik} \leq d_{ij} \\ \Rightarrow & |d_{ik} - d_{jk}| \leq d_{ij} \end{aligned}$$

If valid $\forall k$ then valid for \max_k

- ▶ $\max |d_{ik} - d_{jk}|$ over $k \leq n$ achieved when $k \in \{i, j\}$
 $\Rightarrow \|x_i - x_j\|_\infty = d_{ij}$

Subsection 2

Dimension reduction

Schoenberg's theorem

- ▶ [I. Schoenberg, *Remarks to Maurice Fréchet's article "Sur la définition axiomatique d'une classe d'espaces distanciés vectoriellement applicable sur l'espace de Hilbert"*, Ann. Math., 1935]
- ▶ **Question:** Given $n \times n$ symmetric matrix D , what are necessary and sufficient conditions s.t. D is a Euclidean DM (EDM) corresponding to n points $x_1, \dots, x_n \in \mathbb{R}^K$ with K minimum?

- ▶ **Necessary and sufficient conditions for an EDM**
Thm.

$D = (d_{ij})$ is an EDM iff $\frac{1}{2}(d_{1i}^2 + d_{1j}^2 - d_{ij}^2 \mid 2 \leq i, j \leq n)$ is PSD (of rank K)

- ▶ Yields important result in data science:
Classic Multidimensional Scaling

Gram matrices and EDMs

- ▶ **Realization:** $n \times K$ matrix $x = (x_1, \dots, x_n) \subseteq \mathbb{R}^K$
- ▶ **Gram matrix of x :** $G = xx^\top = (x_i \cdot x_j)$
Lemma: (i) $G \succeq 0$; (ii) each $M \succeq 0$ is a Gram matrix of some x
- ▶ **Theorem:** given rlx x , Gram matrix G and EDM D satisfy

$$G = -\frac{1}{2}JD^2J \quad (\S)$$

- ▶ In the theorem, $D^2 = (d_{ij}^2)$ and

$$J = I_n - \frac{1}{n}\mathbf{1}\mathbf{1}^\top = \begin{pmatrix} 1 - \frac{1}{n} & -\frac{1}{n} & \dots & -\frac{1}{n} \\ -\frac{1}{n} & 1 - \frac{1}{n} & \dots & -\frac{1}{n} \\ \vdots & \vdots & \ddots & \vdots \\ -\frac{1}{n} & -\frac{1}{n} & \dots & 1 - \frac{1}{n} \end{pmatrix}$$

- ▶ This is a variant of Schoenberg's theorem

Multidimensional scaling (MDS)

- ▶ Often get approximate EDMs \tilde{D} from raw data (i.e. matrices that are not EDMs, but they are “not too far”) *(they measure dissimilarities, discrepancies, differences)*
- ▶ $\tilde{G} = -\frac{1}{2}J\tilde{D}^2J$ is an approximate Gram matrix
- ▶ Approximate Gram \Rightarrow spectral decomposition $P\tilde{\Lambda}P^\top$ has $\tilde{\Lambda} \not\geq 0$
- ▶ Let Λ be a PSD diagonal matrix closest to $\tilde{\Lambda}$:
 Λ obtained from $\tilde{\Lambda}$ by zeroing negative components
- ▶ $x = P\sqrt{\Lambda}$ is an “approximate realization” of \tilde{D}
- ▶ Denote $x = \text{MDS}(D)$

Classic MDS: Main result

1. Prove lemma: matrix is Gram iff it is PSD
2. Prove theorem: $G = -\frac{1}{2}JD^2J$

Proof of lemma

▶ $Gram \subseteq PSD$

- ▶ x is an $n \times K$ real matrix
- ▶ $G = xx^\top$ its Gram matrix
- ▶ For each $y \in \mathbb{R}^n$ we have

$$yGy^\top = y(xx^\top)y^\top = (yx)(x^\top y^\top) = (yx)(yx)^\top = \|yx\|_2^2 \geq 0$$

- ▶ $\Rightarrow G \succeq 0$

▶ $PSD \subseteq Gram$

- ▶ Let $G \succeq 0$ be $n \times n$
- ▶ *Spectral decomposition*: $G = P\Lambda P^\top$
(P orthogonal, $\Lambda \geq 0$ diagonal)
- ▶ $\Lambda \geq 0 \Rightarrow \sqrt{\Lambda} \in \mathbb{R}^{n \times n}$
- ▶ $G = P\Lambda P^\top = (P\sqrt{\Lambda})(\sqrt{\Lambda}^\top P^\top) = (P\sqrt{\Lambda})(P\sqrt{\Lambda})^\top$
- ▶ Let $x = P\sqrt{\Lambda}$, then G is the Gram matrix of x

Proof of theorem (1/2)

- ▶ Let $G = xx^\top$, translate x so that centroid $\frac{1}{n} \sum_j x_j = 0$
- ▶ Expand: $d_{ij}^2 = \|x_i - x_j\|_2^2 = (x_i - x_j)(x_i - x_j) = x_i x_i + x_j x_j - 2x_i x_j$ (*)
- ▶ Aim at “inverting” (*) to express $x_i x_j$ in function of d_{ij}^2
- ▶ Sum (*) over i : $\sum_i d_{ij}^2 = \sum_i x_i x_i + n x_j x_j - 2x_j \sum_i x_i$ $\xrightarrow{0 \text{ by zero centroid}}$
- ▶ Similarly for j and divide by n , get:

$$\frac{1}{n} \sum_{i \leq n} d_{ij}^2 = \frac{1}{n} \sum_{i \leq n} x_i x_i + x_j x_j \quad (\dagger)$$

$$\frac{1}{n} \sum_{j \leq n} d_{ij}^2 = x_i x_i + \frac{1}{n} \sum_{j \leq n} x_j x_j \quad (\ddagger)$$

- ▶ Sum (\ddagger) over j , get:

$$\frac{1}{n} \sum_{i,j} d_{ij}^2 = n \frac{1}{n} \sum_i x_i x_i + \sum_j x_j x_j = 2 \sum_i x_i x_i$$

- ▶ Divide by n , get:

$$\frac{1}{n^2} \sum_{i,j} d_{ij}^2 = \frac{2}{n} \sum_i x_i x_i \quad (**)$$

Proof of theorem (2/2)

- ▶ Rearrange (*), (†), (‡) as follows:

$$2x_i x_j = x_i x_i + x_j x_j - d_{ij}^2 \quad (5)$$

$$x_i x_i = \frac{1}{n} \sum_j d_{ij}^2 - \frac{1}{n} \sum_j x_j x_j \quad (6)$$

$$x_j x_j = \frac{1}{n} \sum_i d_{ij}^2 - \frac{1}{n} \sum_i x_i x_i \quad (7)$$

- ▶ Replace LHS of Eq. (6)-(7) in RHS of Eq. (5), get

$$2x_i x_j = \frac{1}{n} \sum_k d_{ik}^2 + \frac{1}{n} \sum_k d_{kj}^2 - d_{ij}^2 - \frac{2}{n} \sum_k x_k x_k$$

- ▶ By (**) replace $\frac{2}{n} \sum_i x_i x_i$ with $\frac{1}{n^2} \sum_{i,j} d_{ij}^2$, get

$$2x_i x_j = \frac{1}{n} \sum_k (d_{ik}^2 + d_{kj}^2) - d_{ij}^2 - \frac{1}{n^2} \sum_{h,k} d_{hk}^2 \quad (§)$$

which expresses $x_i x_j$ in function of D

- ▶ Finally, show RHS of (§) is (i, j) -th entry of $-JD^2J$

See lecture notes, Thm. 10.3.5

Principal Component Analysis (PCA)

- ▶ Given an approximate EDM D
- ▶ find $x = \text{MDS}(D)$
- ▶ However, you want $x = P\sqrt{\Lambda}$ in K dimensions
but $\text{rank}(\Lambda) > K$
- ▶ Only keep K largest components of Λ
zero the rest
- ▶ Get realization in desired space
- ▶ Denote $x = \text{PCA}(D, K)$

Example 3/3

In 2D

In 3D

Subsection 3

Dealing with incomplete metrics

Partial metrics

- ▶ If your metric space is missing some distances
- ▶ Get incomplete EDM D
- ▶ Cannot define vectors $U^D(i)$ in UIE
- ▶ Note: D defines a graph

$$D = \begin{pmatrix} 0 & 1 & \sqrt{2} & 1 \\ 1 & 0 & 1 & ? \\ \sqrt{2} & 1 & 0 & 1 \\ 1 & ? & 1 & 0 \end{pmatrix}$$

- ▶ Complete graph with shortest path (SP) distances:
 $d_{24} = 2$

Floyd-Warshall algorithm 1/2

- ▶ Given $n \times n$ partial matrix D computes *all shortest path lengths*
- ▶ For each triplet z, u, v of vertices in the graph, test:
when going $u \rightarrow v$, is it convenient to pass through z ?

- ▶ If so, then change the path length
- ▶ Complete missing entries d_{uv} in D shortest path lengths $u \rightarrow v$
- ▶ Denote $\bar{D} = \text{FloydWarshall}(D)$

Floyd-Warshall algorithm 2/2

initialization

Subsection 4

The Isomap heuristic

Isomap embedding in \mathbb{R}^K

- ▶ Given a partial EDM D
 1. $\bar{D} = \text{FloydWarshall}(D)$
 2. $x = \text{PCA}(\bar{D}, K)$
- ▶ Intuition of why it works well:

- ▶ Denote $x = \text{Isomap}(D, K)$

[Tenenbaum et al., *Science*, 2000]

Subsection 5

Distance geometry problem

The Distance Geometry Problem (DGP)

Given $K \in \mathbb{N}$ and $G = (V, E, d)$ with $d : E \rightarrow \mathbb{R}_+$,
find $x : V \rightarrow \mathbb{R}^K$ s.t.

$$\forall \{i, j\} \in E \quad \|x_i - x_j\|_2^2 = d_{ij}^2$$

Given a weighted graph

, draw it so edges are drawn as

segments with lengths = weights

Some applications

- ▶ clock synchronization ($K = 1$)
- ▶ sensor network localization ($K = 2$)
- ▶ molecular structure from distance data ($K = 3$)
- ▶ autonomous underwater vehicles ($K = 3$)
- ▶ EDM completion (whatever K)
- ▶ finding graph embeddings (whatever K)

Clock synchronization

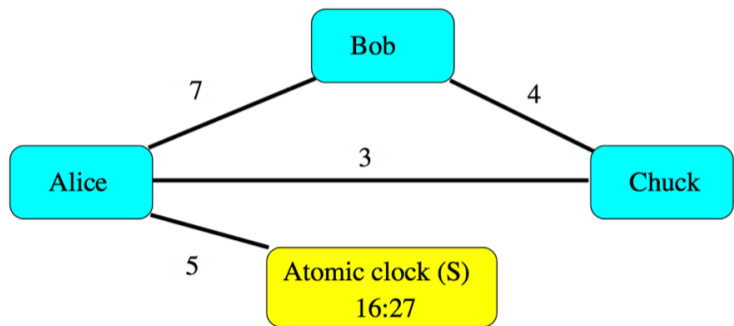

From [Singer, *Appl. Comput. Harmon. Anal.* 2011]

Determine a set of unknown timestamps from partial measurements of their time differences

- ▶ $K = 1$
- ▶ V : timestamps
- ▶ $\{u, v\} \in E$ if known time difference between u, v
- ▶ d : values of the time differences

Used in time synchronization of distributed networks

Clock synchronization

Sensor network localization

From [Yemini, *Proc. CDSN*, 1978]

The positioning problem arises when it is necessary to locate a set of geographically distributed objects using measurements of the distances between some object pairs

- ▶ $K = 2$
- ▶ V : (mobile) sensors
- ▶ $\{u, v\} \in E$ iff distance between u, v is measured
- ▶ d : distance values

Used whenever GPS not viable (e.g. underwater)

$d_{uv} \propto$ battery consumption in P2P communication betw. u, v

Sensor network localization

Molecular structure from distance data

From [Liberti et al., *SIAM Rev.*, 2014]

- ▶ $K = 3$
- ▶ V : atoms
- ▶ $\{u, v\} \in E$ iff distance between u, v is known
- ▶ d : distance values

Used whenever X-ray crystallography does not apply (e.g. liquid)
Covalent bond lengths and angles known precisely
Distances $\lesssim 5.5$ measured approximately by NMR

Graph embeddings

- ▶ Relational knowledge best represented by graphs
- ▶ *We have fast algorithms for clustering vectors*
- ▶ **Task:** represent a graph in \mathbb{R}^n
- ▶ “Graph embeddings” and “distance geometry”:
almost synonyms
- ▶ Used in Natural Language Processing (NLP)
obtain “word vectors” & “sentence vectors”

Project idea 2: create a graph-of-words from a sentence, enrich it with semantic distances, then use the DG methods in these lectures to embed the graph in a low-dimensional space; then evaluate sentence similarity using vector angles

Complexity

- ▶ DGP_1 with $d : E \rightarrow \mathbb{Q}_+$ is in **NP**
 - ▶ if instance YES \exists realization $x \in \mathbb{R}^{n \times 1}$
 - ▶ if some component $x_i \notin \mathbb{Q}$ translate x so $x_i \in \mathbb{Q}$
 - ▶ consider some other x_j
 - ▶ let $\ell = |\text{sh. path } p : i \rightarrow j| = \sum_{\{u,v\} \in p} (-1)^{s_{uv}} d_{uv} \in \mathbb{Q}$
for some $s_{uv} \in \{0, 1\}$
 - ▶ then $x_j = x_i \pm \ell \rightarrow x_j \in \mathbb{Q} (\forall j)$
 - ▶ \Rightarrow polytime verification of

$$\forall \{i, j\} \in E \quad |x_i - x_j| = d_{ij}$$

- ▶ DGP_K may not be in **NP** for $K > 1$
don't know how to polytime check $\|x_i - x_j\|_2 = d_{ij}$ for $x \notin \mathbb{Q}^{nK}$

Hardness

PARTITION is NP-hard

Given $a = (a_1, \dots, a_n) \in \mathbb{N}^n$, $\exists I \subseteq \{1, \dots, n\}$ s.t. $\sum_{i \in I} a_i = \sum_{i \notin I} a_i$?

- ▶ Reduce PARTITION to DGP_1 on single-cycle graphs
- ▶ $a \rightarrow$ cycle C
 $V(C) = \{1, \dots, n\}$, $E(C) = \{\{1, 2\}, \dots, \{n, 1\}\}$
- ▶ For $i < n$ let $d_{i,i+1} = a_i$
For $i = n$, let $d_{n,n+1} = d_{n1} = a_n$
- ▶ *E.g. for $a = (1, 4, 1, 3, 3)$, get cycle graph:*

PARTITION is YES \Rightarrow DGP₁ is YES

- ▶ **Given:** $I \subset \{1, \dots, n\}$ s.t. $\sum_{i \in I} a_i = \sum_{i \notin I} a_i$
- ▶ **Construct:** realization x of C in \mathbb{R}
 1. $x_1 = 0$ // start
 2. **induction step:** suppose x_i known
if $i \in I$
 - let $x_{i+1} = x_i + d_{i,i+1}$ // go rightelse
 - let $x_{i+1} = x_i - d_{i,i+1}$ // go left
- ▶ **Correctness proof:** by the same induction
but careful when $i = n$: have to show $x_{n+1} = x_1$

PARTITION is YES \Rightarrow DGP₁ is YES

Proof that $x_{n+1} = x_1$:

$$\begin{aligned}(1) &= \sum_{i \in I} (x_{i+1} - x_i) = \sum_{i \in I} d_{i,i+1} = \\ &= \sum_{i \in I} a_i = \sum_{i \notin I} a_i = \\ &= \sum_{i \notin I} d_{i,i+1} = \sum_{i \notin I} (x_i - x_{i+1}) = (2)\end{aligned}$$

$$\begin{aligned}(1) = (2) &\Rightarrow \sum_{i \in I} (x_{i+1} - x_i) = \sum_{i \notin I} (x_i - x_{i+1}) \Rightarrow \sum_{i \leq n} (x_{i+1} - x_i) = 0 \\ &\Rightarrow (x_{n+1} - x_n) + (x_n - x_{n-1}) + \cdots + (x_3 - x_2) + (x_2 - x_1) = 0 \\ &\hspace{20em} \Rightarrow x_{n+1} = x_1\end{aligned}$$

PARTITION is NO \Rightarrow DGP₁ is NO

- ▶ By contradiction: suppose DGP₁ is YES, x realization of C
- ▶ $F = \{\{u, v\} \in E(C) \mid x_u \leq x_v\}$,
 $E(C) \setminus F = \{\{u, v\} \in E(C) \mid x_u > x_v\}$
- ▶ Trace x_1, \dots, x_n : follow edges in F (\rightarrow) and in $E(C) \setminus F$ (\leftarrow)

DGP₁ instance is YES \Rightarrow

$$\sum_{\{u,v\} \in F} (x_v - x_u) = \sum_{\{u,v\} \notin F} (x_u - x_v)$$

$$\sum_{\{u,v\} \in F} |x_u - x_v| = \sum_{\{u,v\} \notin F} |x_u - x_v|$$

$$\sum_{\{u,v\} \in F} d_{uv} = \sum_{\{u,v\} \notin F} d_{uv}$$

- ▶ Let $J = \{i < n \mid \{i, i+1\} \in F\} \cup \{n \mid \{n, 1\} \in F\}$

$$\Rightarrow \sum_{i \in J} a_i = \sum_{i \notin J} a_i$$

- ▶ So J solves Partition instance, contradiction
- ▶ \Rightarrow DGP is NP-hard, DGP₁ is NP-complete

Number of solutions

- ▶ (G, K) : DGP instance
- ▶ $\tilde{X} \subseteq \mathbb{R}^{Kn}$: set of solutions
- ▶ *Congruence*: composition of translations, rotations, reflections
- ▶ C = set of congruences in \mathbb{R}^K
- ▶ $x \sim y$ means $\exists \rho \in C$ ($y = \rho x$):
distances in x are preserved in y through ρ
- ▶ \Rightarrow if $|\tilde{X}| > 0$, $|\tilde{X}| = 2^{N_0}$

Number of solutions modulo congruences

- ▶ Congruence is an *equivalence relation* \sim on \tilde{X} (reflexive, symmetric, transitive)

- ▶ Partitions \tilde{X} into *equivalence classes*
- ▶ $X = \tilde{X}/\sim$
sets of representatives of equivalence classes
- ▶ **Focus on $|X|$ rather than $|\tilde{X}|$**

Rigidity, flexibility and $|X|$

- ▶ infeasible $\Leftrightarrow |X| = 0$
- ▶ rigid graph $\Leftrightarrow |X| < \aleph_0$
- ▶ globally rigid graph $\Leftrightarrow |X| = 1$
- ▶ flexible graph $\Leftrightarrow |X| = 2^{\aleph_0}$
- ▶ $|X| = \aleph_0$: impossible by Milnor's theorem

Milnor's theorem implies $|X| \neq \aleph_0$

- ▶ System S of polynomial equations of degree 2

$$\forall i \leq m \quad p_i(x_1, \dots, x_{nK}) = 0$$

- ▶ Let X be the set of $x \in \mathbb{R}^{nK}$ satisfying S
- ▶ **Number of connected components of X is $O(3^{nK})$**
[Milnor 1964]
- ▶ Assume $|X|$ is countable; then G cannot be flexible
 \Rightarrow *each incongruent rlx is in a separate component*
 \Rightarrow by Milnor's theorem, there's finitely many of them

Examples

$$V^1 = \{1, 2, 3\}$$

$$E^1 = \{\{u, v\} \mid u < v\}$$

$$d^1 = 1$$

ρ congruence in \mathbb{R}^2

$\Rightarrow \rho x$ valid realization

$$|X| = 1$$

$$V^2 = V^1 \cup \{4\}$$

$$E^2 = E^1 \cup \{\{1, 4\}, \{2, 4\}\}$$

$$d^2 = 1 \wedge d_{14} = \sqrt{2}$$

ρ reflects x_4 wrt $\overline{x_1, x_2}$

$\Rightarrow \rho x$ valid realization

$$|X| = 2 \quad (\triangle, \diamond)$$

$$V^3 = V^2$$

$$E^3 = \{\{u, u+1\} \mid u \leq 3\} \cup \{1, 4\}$$

$$d^1 = 1$$

ρ rotates $\overline{x_2x_3}$, $\overline{x_1x_4}$ by θ

$\Rightarrow \rho x$ valid realization

$|X|$ is uncountable

$$(\square, \diamond, \text{parallelogram}, \text{trapezoid}, \dots)$$

Subsection 6

Distance geometry in MP

DGP formulations and methods

- ▶ System of equations
- ▶ Unconstrained global optimization (GO)
- ▶ Constrained global optimization
- ▶ SDP relaxations and their properties
- ▶ Diagonal dominance
- ▶ Concentration of measure in SDP
- ▶ Isomap for DGP

System of quadratic equations

$$\forall \{u, v\} \in E \quad \|x_u - x_v\|^2 = d_{uv}^2 \quad (8)$$

Computationally: useless
reformulate using slacks:

$$\min_{x,s} \left\{ \sum_{\{u,v\} \in E} s_{uv}^2 \mid \forall \{u, v\} \in E \quad \|x_u - x_v\|^2 = d_{uv}^2 + s_{uv} \right\} \quad (9)$$

Unconstrained Global Optimization

$$\min_x \sum_{\{u,v\} \in E} (\|x_u - x_v\|^2 - d_{uv}^2)^2 \quad (10)$$

Globally optimal obj. fun. value of (10) is 0 iff x solves (8)

Computational experiments in [Liberti et al., 2006]:

- ▶ GO solvers from >15 years ago
- ▶ randomly generated protein data: ≤ 50 atoms
- ▶ cubic crystallographic grids: ≤ 64 atoms

Constrained global optimization

▶ $\min_x \sum_{\{u,v\} \in E} \left| \|x_u - x_v\|^2 - d_{uv}^2 \right|$ exactly reformulates (8)

▶ Relax objective f to concave part, remove constant term, rewrite $\min -f$ as $-\max f$

$$\min_x \sum_{uv} (d_{uv}^2 - \|x_u - x_v\|_2^2) = \sum_{uv} d_{uv}^2 - \max_x \sum_{uv} \|x_u - x_v\|_2^2$$

▶ Reformulate convex part of obj. fun. to convex constraints

$$\forall \{u, v\} \in E \quad \|x_u - x_v\|_2^2 \leq d_{uv}^2$$

▶ Exact reformulation (*“push-and-pull”*)

$$\left. \begin{array}{l} \max_x \sum_{\{u,v\} \in E} \|x_u - x_v\|^2 \\ \forall \{u, v\} \in E \quad \|x_u - x_v\|^2 \leq d_{uv}^2 \end{array} \right\} \quad (11)$$

Theorem (Activity)

At a glob. opt. x^ of a YES instance, all constraints of (11) are active*

Push-and-pull linearization

Linearization of nonlinear terms $\|x_i - x_j\|_2^2$
for all $\{i, j\} \in E$:

$$\Rightarrow \forall \{i, j\} \in E \quad \|x_i\|_2^2 + \|x_j\|_2^2 - 2x_i \cdot x_j = d_{ij}^2$$

$$\Rightarrow \begin{cases} \forall \{i, j\} \in E & X_{ii} + X_{jj} - 2X_{ij} = d_{ij}^2 \\ & X = x x^\top \end{cases}$$

Relaxation

$$X = x x^\top$$

$$\Rightarrow X - x x^\top = 0$$

$$\text{(relax)} \Rightarrow X - x x^\top \succeq 0$$

$$\text{Schur}(X, x) = \begin{pmatrix} I_K & x^\top \\ x & X \end{pmatrix} \succeq 0$$

If x does not appear elsewhere \Rightarrow get rid of it (e.g. choose $x = 0$):

replace $\text{Schur}(X, x) \succeq 0$ by $X \succeq 0$

SDP relaxation

- ▶ Relaxation:

$$\begin{aligned} & \min F \bullet X \\ \forall \{i, j\} \in E & \quad X_{ii} + X_{jj} - 2X_{ij} = d_{ij}^2 \\ & \quad X \succeq 0 \end{aligned}$$

- ▶ Note SDP \equiv linear obj. s.t. linear constrs \wedge PSD cone
- ▶ DGP linearization/relaxation only defines feasible set
- ▶ Note $F \bullet X = \text{tr}(F^\top X) = \sum_{ij} F_{ij} X_{ij}$
- ▶ Can we choose a “good” objective function F ?

Some possible objective functions

- ▶ For protein conformation:

$$\min \sum_{\{i,j\} \in E} (X_{ii} + X_{jj} - 2X_{ij})$$

with = changed to \geq in constraints (*or max and \leq*)
“push-and-pull” relaxation

- ▶ [Ye, 2003], application to wireless sensors localization

$$\min \text{tr}(X)$$

$\text{tr}(X) = \text{tr}(P^{-1}\Lambda P) = \text{tr}(P^{-1}P\Lambda) = \text{tr}(\Lambda) = \sum_i \lambda_i$
 \Rightarrow *hope to minimize rank*

- ▶ How about “just random”?

How do you choose?

for want of some better criterion...

TEST!

- ▶ Download protein files from Protein Data Bank (PDB)
they contain atom realizations
- ▶ Mimick a Nuclear Magnetic Resonance experiment
Keep only pairwise distances < 5.5
- ▶ Try and reconstruct the protein shape from those weighted graphs
- ▶ Quality evaluation of results:

- ▶
$$\text{LDE}(x) = \max_{\{i,j\} \in E} | \|x_i - x_j\| - d_{ij} |$$

- ▶
$$\text{MDE}(x) = \frac{1}{|E|} \sum_{\{i,j\} \in E} | \|x_i - x_j\| - d_{ij} |$$

Empirical choice

- ▶ *Ye* faster but often imprecise
- ▶ *Random* good but nondeterministic
- ▶ *Push-and-Pull*: can relax $X_{ii} + X_{jj} - 2X_{ij} = d_{ij}^2$ to $X_{ii} + X_{jj} - 2X_{ij} \geq d_{ij}^2$
easier to satisfy feasibility, useful later on
- ▶ *Heuristic*: add $+\eta \text{tr}(X)$ to objective, with $\eta \ll 1$
might help minimize solution rank
- ▶ $\min \sum_{\{i,j\} \in E} (X_{ii} + X_{jj} - 2X_{ij}) + \eta \text{tr}(X)$
appears to be a good objective function

*When solving real problems maths may not be enough
use common sense too*

Retrieving realizations in \mathbb{R}^K

- ▶ SDP relaxation yields $n \times n$ PSD matrix X^*
- ▶ We need $n \times K$ realization matrix x^*
- ▶ Recall $PSD \Leftrightarrow Gram$
- ▶ Apply PCA to X^* , keep K largest comps, get x'
- ▶ This yields solutions with errors
- ▶ Use x' as starting pt for local NLP solver

Later on: Barvinok's Naive Algorithm, an SDP-specific alternative to PCA

When SDP solvers hit their size limit

- ▶ **SDP solver: technological bottleneck**
- ▶ Can we use an LP solver instead?
- ▶ Diagonally Dominant (DD) matrices are PSD
- ▶ Not *vice versa*: inner approximate PSD cone $Y \succeq 0$
- ▶ *Idea by A.A. Ahmadi [Ahmadi & Hall 2015]*

Diagonally dominant matrices

$n \times n$ symmetric matrix X is DD if

$$\forall i \leq n \quad X_{ii} \geq \sum_{j \neq i} |X_{ij}|.$$

E.g.
$$\begin{pmatrix} 1 & 0.1 & -0.2 & 0 & 0.04 & 0 \\ 0.1 & 1 & -0.05 & 0.1 & 0 & 0 \\ -0.2 & -0.05 & 1 & 0.1 & 0.01 & 0 \\ 0 & 0.1 & 0.1 & 1 & 0.2 & 0.3 \\ 0.04 & 0 & 0.01 & 0.2 & 1 & -0.3 \\ 0 & 0 & 0 & 0.3 & -0.3 & 1 \end{pmatrix}$$

Gershgorin's circle theorem

- ▶ Let A be symmetric $n \times n$
- ▶ $\forall i \leq n$ let $R_i = \sum_{j \neq i} |A_{ij}|$ and $I_i = [A_{ii} - R_i, A_{ii} + R_i]$
- ▶ Then $\forall \lambda$ eigenvalue of $A \quad \exists i \leq n$ s.t. $\lambda \in I_i$

Proof

- ▶ Let λ be an eigenvalue of A with eigenvector \mathbf{y}
- ▶ Normalize \mathbf{y} s.t. $\exists i \leq n \quad \mathbf{y}_i = 1$ and $\forall j \neq i \quad |\mathbf{y}_j| \leq 1$
let $i = \arg \max_j |\mathbf{y}_j|$, divide \mathbf{y} by $\text{sgn}(\mathbf{y}_i)|\mathbf{y}_i|$. Now fix i :
- ▶ $A\mathbf{y} = \lambda\mathbf{y} \Rightarrow \sum_{j \leq n: j \neq i} A_{ij}\mathbf{y}_j + A_{ii}\mathbf{y}_i = \sum_{j \leq n: j \neq i} A_{ij}\mathbf{y}_j + A_{ii} = \lambda\mathbf{y}_i = \lambda$
- ▶ Hence $\sum_{j \leq n: j \neq i} A_{ij}\mathbf{y}_j = \lambda - A_{ii}$
- ▶ Triangle+Cauchy-Schwarz inequalities & $\forall j \neq i \quad |\mathbf{y}_j| \leq 1 \Rightarrow$
 $|\lambda - A_{ii}| = \left| \sum_{j \leq n: j \neq i} A_{ij}\mathbf{y}_j \right| \leq \sum_{j \leq n: j \neq i} |A_{ij}| |\mathbf{y}_j| \leq \sum_{j \leq n: j \neq i} |A_{ij}| = R_i$
hence $\lambda \in I_i$

DD \Rightarrow PSD

- ▶ Assume A is DD, λ an eigenvalue of A
- ▶ $\Rightarrow \forall i \leq n \quad A_{ii} \geq \sum_{j \neq i} |A_{ij}| = R_i$
- ▶ $\Rightarrow \forall i \leq n \quad A_{ii} - R_i \geq 0$
- ▶ By Gershgorin's circle theorem $\lambda \geq 0$
- ▶ $\Rightarrow A$ is PSD

DD Linearization

$$\forall i \leq n \quad X_{ii} \geq \sum_{j \neq i} |X_{ij}| \quad (*)$$

- ▶ linearize $|\cdot|$ by additional matrix var T
 \Rightarrow write $|X|$ as T

- ▶ $\Rightarrow (*)$ becomes

$$X_{ii} \geq \sum_{j \neq i} T_{ij}$$

- ▶ add “sandwich” constraints $-T \leq X \leq T$
- ▶ Can easily prove $(*)$ in case $X \geq 0$ or $X \leq 0$:

$$X_{ii} \geq \sum_{j \neq i} T_{ij} \geq \sum_{j \neq i} X_{ij}$$

$$X_{ii} \geq \sum_{j \neq i} T_{ij} \geq \sum_{j \neq i} -X_{ij}$$

- ▶ General case requires polyhedral analysis

The issue with inner approximations

DDP could be infeasible!

Exploit push-and-pull

- ▶ Enlarge the feasible region
- ▶ From

$$\forall \{i, j\} \in E \quad X_{ii} + X_{jj} - 2X_{ij} = d_{ij}^2$$

- ▶ Use “push” objective $\min \sum_{ij \in E} X_{ii} + X_{jj} - 2X_{ij}$
- ▶ Relax to

$$\forall \{i, j\} \in E \quad X_{ii} + X_{jj} - 2X_{ij} \geq d_{ij}^2$$

Hope to achieve LP feasibility

DDP formulation for the DGP

$$\left. \begin{array}{ll} \min & \sum_{\{i,j\} \in E} (X_{ii} + X_{jj} - 2X_{ij}) \\ \forall \{i,j\} \in E & X_{ii} + X_{jj} - 2X_{ij} \geq d_{ij}^2 \\ \forall i \leq n & \sum_{\substack{j \leq n \\ j \neq i}} T_{ij} \leq X_{ii} \\ & -T \leq X \leq T \end{array} \right\}$$

Solve, then retrieve solution in \mathbb{R}^K with PCA

Subsection 7

DGP cones

Cones

- ▶ Set C is a *cone* if:

$$\forall A, B \in C, \alpha, \beta \geq 0 \quad \alpha A + \beta B \in C$$

- ▶ If C is a cone, the *dual cone* is

$$C^* = \{y \mid \forall x \in C \langle x, y \rangle \geq 0\}$$

vectors making acute angles with all elements of C

- ▶ If $C \subset \mathbb{S}_n$ (set $n \times n$ symmetric matrices)

$$C^* = \{Y \mid \forall X \in C (Y \bullet X \geq 0)\}$$

- ▶ A $n \times n$ matrix cone C is *finitely generated* by $\mathcal{X} \subset \mathbb{R}^n$ if

$$\mathcal{X} = \{x_1, \dots, x_p\} \wedge \quad \forall X \in C \exists \delta \in \mathbb{R}_+^p \quad X = \sum_{\ell \leq p} \delta_\ell x_\ell x_\ell^\top$$

Representations of $\mathbb{D}\mathbb{D}$

- ▶ Consider $E_{ii}, E_{ij}^+, E_{ij}^-$ in \mathbb{S}_n
Define $\mathcal{E}_0 = \{E_{ii} \mid i \leq n\}$, $\mathcal{E}_1 = \{E_{ij}^\pm \mid i < j\}$, $\mathcal{E} = \mathcal{E}_0 \cup \mathcal{E}_1$
- ▶ $E_{ii} = \text{diag}(0, \dots, 0, 1_i, 0, \dots, 0)$
- ▶ E_{ij}^+ has minor $\begin{pmatrix} 1_{ii} & 1_{ij} \\ 1_{ji} & 1_{jj} \end{pmatrix}$, 0 elsewhere
- ▶ E_{ij}^- has minor $\begin{pmatrix} 1_{ii} & -1_{ij} \\ -1_{ji} & 1_{jj} \end{pmatrix}$, 0 elsewhere
- ▶ **Thm.** $\mathbb{D}\mathbb{D} = \text{cone generated by } \mathcal{E}$ [Barker & Carlson 1975]
Pf. Rays in \mathcal{E} are extreme, all DD matrices generated by \mathcal{E}
- ▶ **Cor.** $\mathbb{D}\mathbb{D}$ finitely gen. by
 $\mathcal{X}_{\mathbb{D}\mathbb{D}} = \{e_i \mid i \leq n\} \cup \{(e_i \pm e_j) \mid i < j \leq n\}$
Pf. Verify $E_{ii} = e_i e_i^\top$, $E_{ij}^\pm = (e_i \pm e_j)(e_i \pm e_j)^\top$, where e_i is the i -th std basis element of \mathbb{R}^n

Finitely generated dual cone representation

Thm. If C finitely gen. by \mathcal{X} , then

$$C^* = \{Y \in \mathbb{S}^n \mid \forall x \in \mathcal{X} (Y \bullet xx^\top \geq 0)\}$$

recall $C^* \triangleq \{Y \in \mathbb{S}^n \mid \forall X \in C \ Y \bullet X \geq 0\}$

- ▶ (\supseteq) Let Y s.t. $\forall x \in \mathcal{X} (Y \bullet xx^\top \geq 0)$
 - ▶ $\forall X \in C, X = \sum_{x \in \mathcal{X}} \delta_x xx^\top$ (by fin. gen.)
 - ▶ hence $Y \bullet X = \sum_x \delta_x Y \bullet xx^\top \geq 0$ (by defn. of Y)
 - ▶ whence $Y \in C^*$ (by defn. of C^*)
- ▶ (\subseteq) Suppose $Z \in C^* \setminus \{Y \mid \forall x \in \mathcal{X} (Y \bullet xx^\top \geq 0)\}$
 - ▶ then $\exists \mathcal{X}' \subset \mathcal{X}$ s.t. $\forall x \in \mathcal{X}' (Z \bullet xx^\top < 0)$
 - ▶ consider any $Y = \sum_{x \in \mathcal{X}'} \delta_x xx^\top \in C$ with $\delta \geq 0$
 - ▶ then $Z \bullet Y = \sum_{x \in \mathcal{X}'} \delta_x Z \bullet xx^\top < 0$ so $Z \notin C^*$
 - ▶ contradiction $\Rightarrow C^* = \{Y \mid \forall x \in \mathcal{X} (Y \bullet xx^\top \geq 0)\}$

Dual cone constraints

- ▶ **Remark:** for $v \in \mathbb{R}^n$, $X \bullet vv^\top = v^\top X v$
- ▶ Use finitely generated dual cone theorem
- ▶ Decision variable matrix X
- ▶ Constraints:

$$\forall v \in \mathcal{X} \quad v^\top X v \geq 0$$

- ▶ **Cor.** $\text{DD}^* \supset \text{PSD}$
Pf. $X \in \text{PSD}$ iff $\forall v \in \mathbb{R}^n \quad v^\top X v \geq 0$, so certainly valid $\forall v \in \mathcal{X}$
- ▶ If $|\mathcal{X}|$ polysized, get compact formulation
otherwise use column generation
- ▶ $|\mathcal{X}_{\text{DD}}| = |\mathcal{E}| = O(n^2)$

Dual cone DDP formulation for DGP

$$\left. \begin{array}{l} \min \sum_{\{i,j\} \in E} (X_{ii} + X_{jj} - 2X_{ij}) \\ \forall \{i, j\} \in E \quad X_{ii} + X_{jj} - 2X_{ij} = d_{ij}^2 \\ \forall v \in \mathcal{X}_{\text{DD}} \quad v^\top X v \geq 0 \end{array} \right\}$$

► $v^\top X v \geq 0$ for $v \in \mathcal{X}_{\text{DD}}$ equivalent to:

$$\begin{array}{ll} \forall i \leq n & X_{ii} \geq 0 \\ \forall \{i, j\} \notin E & X_{ii} + X_{jj} - 2X_{ij} \geq 0 \\ \forall i < j & X_{ii} + X_{jj} + 2X_{ij} \geq 0 \end{array}$$

Note we went back to equality “pull” constraints (why?)

Quantifier $\forall \{i, j\} \notin E$ should be $\forall i < j$ but we already have those constraints

$\forall \{i, j\} \in E$

Properties

- ▶ SDP relaxes original problem
- ▶ DualDDP relaxes SDP
hence also relaxes original problem
- ▶ Yields tight obj fun bounds w.r.t. SDP
- ▶ Solutions may have large negative rank
in some applications, retrieving feasible solutions may be difficult

Project idea 3: Apply the DG methods seen in these lectures in order to control a fleet of submarine robots (for each time instant $t \in T$ they define a different distance graph)

Subsection 8

Barvinok's Naive Algorithm

Concentration of measure

From [Barvinok, 1997]

The value of a “well behaved” function at a random point of a “big” probability space X is “very close” to the mean value of the function.

and

In a sense, measure concentration can be considered as an extension of the law of large numbers.

Concentration of measure

Given Lipschitz function $f : X \rightarrow \mathbb{R}$ s.t.

$$\forall x, y \in X \quad |f(x) - f(y)| \leq L\|x - y\|_2$$

for some $L \geq 0$, there is *concentration of measure* if \exists constants c, C s.t.

$$\forall \varepsilon > 0 \quad \mathbf{P}_x(|f(x) - \mathbf{E}(f)| > \varepsilon) \leq c e^{-C\varepsilon^2/L^2}$$

where $\mathbf{E}(\cdot)$ is w.r.t. given Borel measure μ over X

\equiv “*discrepancy from mean is unlikely*”

Barvinok's theorem

Consider:

- ▶ for each $k \leq m$, manifolds $\mathcal{X}_k = \{x \in \mathbb{R}^n \mid x^\top Q^k x = a_k\}$
where $m \leq \text{poly}(n)$
- ▶ feasibility problem $F \equiv [\bigcap_{k \leq m} \mathcal{X}_k \stackrel{?}{\neq} \emptyset]$
- ▶ SDP relaxation $\forall k \leq m (Q^k \bullet X = a_k) \wedge X \succeq 0$ with soln. \bar{X}
- ▶ **Algorithm:** $T \leftarrow \text{factor}(\bar{X}); \quad y \sim \mathcal{N}^n(0, 1); \quad x' \leftarrow Ty$

Then:

- ▶ $\exists c > 0, n_0 \in \mathbb{N}$ such that $\forall n \geq n_0$

$$\text{Prob} \left(\forall k \leq m \quad \text{dist}(x', \mathcal{X}_k) \leq c \sqrt{\|\bar{X}\|_2 \ln n} \right) \geq 0.9.$$

Algorithmic application

- ▶ x' is “close” to each \mathcal{X}_k : *try local descent from x'*
- ▶ \Rightarrow Feasible QP solution from an SDP relaxation

Elements of Barvinok's formula

$$\text{Prob} \left(\forall k \leq m \quad \text{dist}(x', \mathcal{X}_k) \leq c \sqrt{\|\bar{X}\|_2 \ln n} \right) \geq 0.9.$$

- ▶ $\sqrt{\|\bar{X}\|_2}$ arises from T (a factor of \bar{X})
- ▶ $\sqrt{\ln n}$ arises from concentration of measure
- ▶ 0.9 follows by adjusting parameter values in “union bound”

Application to the DGP

- ▶ $\forall \{i, j\} \in E \quad \mathcal{X}_{ij} = \{x \mid \|x_i - x_j\|_2^2 = d_{ij}^2\}$
 - ▶ DGP can be written as $\bigcap_{\{i,j\} \in E} \mathcal{X}_{ij} \stackrel{?}{\neq} \emptyset$
 - ▶ SDP relaxation $X_{ii} + X_{jj} - 2X_{ij} = d_{ij}^2 \wedge X \succeq 0$ with soln. \bar{X}
-
- ▶ Difference with Barvinok: $x \in \mathbb{R}^{Kn}, \text{rk}(\bar{X}) \leq K$
 - ▶ IDEA: sample $y \sim N^{nK}(0, \frac{1}{\sqrt{K}})$
 - ▶ **Thm.** Barvinok's theorem works in rank K

Proof structure

- ▶ Show that, on average, $\forall k \leq m \operatorname{tr}((Ty)^\top Q^k(Ty)) = Q^k \bullet \bar{X} = a_k$
 - ▶ compute multivariate integrals
 - ▶ bilinear terms disappear because y normally distributed
 - ▶ decompose multivariate int. to a sum of univariate int.
- ▶ Exploit concentration of measure to show errors happen rarely
 - ▶ a couple of technical lemmata yielding bounds
 - ▶ \Rightarrow bound Gaussian measure μ of ε -neighbourhoods of

$$A_i^- = \{y \in \mathbb{R}^{n \times K} \mid Q^i(Ty) \leq Q^i \bullet \bar{X}\}$$

$$A_i^+ = \{y \in \mathbb{R}^{n \times K} \mid Q^i(Ty) \geq Q^i \bullet \bar{X}\}$$

$$A_i = \{y \in \mathbb{R}^{n \times K} \mid Q^i(Ty) = Q^i \bullet \bar{X}\}.$$

- ▶ use “union bound” for measure of $A_i^-(\varepsilon) \cap A_i^+(\varepsilon)$
- ▶ show $A_i^-(\varepsilon) \cap A_i^+(\varepsilon) = A_i(\varepsilon)$
- ▶ use “union bound” to measure intersections of $A_i(\varepsilon)$
- ▶ appropriate values for some parameters \Rightarrow result

The heuristic

1. Solve SDP relaxation of DGP, get soln. \bar{X}
use DDP+LP if SDP+IPM too slow
2.
 - a. $T = \text{factor}(\bar{X})$
 - b. $y \sim \mathbf{N}^{nK}(0, \frac{1}{\sqrt{K}})$
 - c. $x' = Ty$
3. Use x' as starting point for a local NLP solver on formulation

$$\min_x \sum_{\{i,j\} \in E} (\|x_i - x_j\|^2 - d_{ij}^2)^2$$

and return improved solution x

Subsection 9

Isomap revisited

Isomap for the DGP

- ▶ Given DGP instance $(K, G = (V, E, d))$:
 1. D = square weighted adjacency matrix of G
 2. \bar{D} = completion of D
 3. $x' = \text{PCA}(\bar{D}, K)$
 4. x = locally optimal solution closest to x'

- ▶ Step 4 is the “refinement step”
calls a local solver for the DGP with starting point x'
- ▶ Vary Step 2 to generate Isomap-based heuristics

Variants for Step 2

- A. Floyd-Warshall all-shortest-paths algorithm on G
(classic Isomap)
- B. Find a spanning tree (SPT) of G and compute a random realization in $\bar{x} \in \mathbb{R}^K$, use its sqEDM
- C. Solve a push-and-pull SDP/DDP/DualDDP to find a realization $x' \in \mathbb{R}^n$, use its sqEDM

Project idea 4: implement and test at least 6 different variants of Isomap for DGP: the three above, and at least three new ones of your own conception

Subsection 10

Summary

Matrix reformulations

- ▶ Quadratic nonconvex too difficult?
- ▶ *Solve SDP relaxation*
- ▶ SDP relaxation too large?
- ▶ *Solve DDP approximation*
- ▶ Get $n \times n$ matrix solution, need $K \times n!$

Solution rank reduction methods

- ▶ Multidimensional Scaling (MDS)
- ▶ Principal Component Analysis (PCA)
- ▶ Barvinok's naive algorithm (BNA)
- ▶ Isomap

All provide good starting points for local solvers

Can also use them for general dimensionality reduction:
they map n vectors in $\mathbb{R}^n \rightarrow n$ vectors in \mathbb{R}^K

Summary

Random projections in LP

- Random projection theory
- Projecting LP feasibility
- Projecting LP optimality
- Solution retrieval
- Application to quantile regression

Sparsity and ℓ_1 minimization

- Motivation
- Basis pursuit
- Theoretical results
- Application to noisy channel encoding
- Improvements

Kissing Number Problem

- Lower bounds
- Upper bounds from SDP?
- Gregory's upper bound
- Delsarte's upper bound
- Pfender's upper bound

Clustering in Natural Language

- Clustering on graphs
- Clustering in Euclidean spaces
- Distance instability
- MP formulations
- Random projections again

The gist of random projections (RP)

- ▶ Let A be a $m \times n$ data matrix (columns in \mathbb{R}^m , $m \gg 1$)
- ▶ T short & fat, normally sampled componentwise

$$\underbrace{\begin{pmatrix} \vdots & \vdots \\ \vdots & \vdots \\ \vdots & \vdots \end{pmatrix}}_T \underbrace{\begin{pmatrix} \vdots & \vdots & \vdots \\ \vdots & \vdots & \vdots \\ \vdots & \vdots & \vdots \end{pmatrix}}_A = \underbrace{\begin{pmatrix} \vdots & \vdots & \vdots \\ \vdots & \vdots & \vdots \\ \vdots & \vdots & \vdots \end{pmatrix}}_{TA}$$

- ▶ Then $\forall i < j \ \|A_i - A_j\|_2 \approx \|TA_i - TA_j\|_2$ “wahp”

“wahp” = “with arbitrarily high probability”

the probability of E_k (depending on some parameter k)
approaches 1 “*exponentially fast*” as k increases

$$\mathbf{P}(E_k) \geq 1 - O(e^{-k})$$

Johnson-Lindenstrauss Lemma (JLL)

Thm.

Given $A \subseteq \mathbb{R}^m$ with $|A| = n$ and $\varepsilon > 0$ there is $k = O(\frac{1}{\varepsilon^2} \ln n)$ and a $k \times m$ matrix T s.t.

$$\forall x, y \in A \quad (1 - \varepsilon)\|x - y\| \leq \|Tx - Ty\| \leq (1 + \varepsilon)\|x - y\|$$

If $k \times m$ matrix T is sampled componentwise from $\mathbf{N}(0, \frac{1}{\sqrt{k}})$, then

$$\mathbf{P}(A \text{ and } TA \text{ approximately congruent}) \geq \frac{1}{n}$$

(nontrivial) — result follows by probabilistic method

Note that $1/\sqrt{k}$ is the standard deviation, not the variance

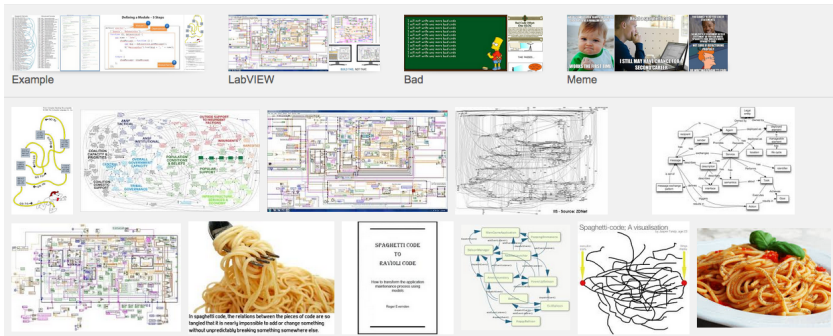

In practice

- ▶ $\mathbf{P}(A \text{ and } TA \text{ approximately congruent}) \geq \frac{1}{n}$
- ▶ re-sampling sufficiently many times gives wahp
- ▶ Empirically, sample T few times (once will do)
 $\mathbb{E}_T(\|Tx - Ty\|) = \|x - y\|$
probability of error decreases wahp

Surprising fact:

k is independent of the original number of dimensions m

Clustering Google images

[L. & Lavor, 2017]

Clustering without RPs

```
VHimg = Map[Flatten[ImageData[#]] &, Himg];
```

```
VHcl = Timing[ClusteringComponents[VHimg, 3, 1]]
```

```
Out[29]= {0.405908, {1, 2, 2, 2, 2, 2, 3, 2, 2, 2, 3}}
```

Too slow!

Clustering with RPs

```
Get["Projection.m"];  
VKing = JohnsonLindenstrauss[VHimg, 0.1];  
VKcl = Timing[ClusteringComponents[VKing, 3, 1]]  
Out[34]= {0.002232, {1, 2, 2, 2, 2, 2, 3, 2, 2, 2, 3}}
```

From 0.405s CPU time to 0.00232s
Same clustering

Projecting formulations

- ▶ Given:
 - ▶ $F(p, x)$: MP formulation with params p & vars x
 - ▶ $\text{sol}(F)$: solution of F
 - ▶ \mathcal{C} : formulation class (e.g. LP, NLP, MILP, MINLP)
 - ▶ Given RP T , define $TF(p, x)$ as
$$F(Tp, x) \text{ or } F(Tp, Tx)$$
 - ▶ Want to show: $\forall F \in \mathcal{C} \text{ sol}(F) \approx \text{sol}(TF)$ wahp
 - ▶ Issues:
 - ▶ RPs project points not vars/constrs
 - ▶ approximate congruence \neq feasibility/optimality
 - ▶ JLL applies to finite pt sets, vars encode ∞ pts
-
- ▶ Today we see this for $\mathcal{C} = \text{LP}$
 - ▶ Can also be applied to QP, SDP, QCQP, and more

Subsection 1

Random projection theory

The shape of a set of points

► **Lose dimensions but not too much accuracy**

Given $A_1, \dots, A_n \in \mathbb{R}^m$ find $k \ll m$ and $A'_1, \dots, A'_n \in \mathbb{R}^k$ s.t.

A and A' “have almost the same shape”

► What is the shape of a set of points?

congruence \Leftrightarrow *same shape*: $\|A_i - A_j\| = \|A'_i - A'_j\|$

► *Approximate congruence* \equiv *small distortion*:

A, A' have almost the same shape if

$$\forall i < j \leq n \quad (1 - \varepsilon)\|A_i - A_j\| \leq \|A'_i - A'_j\| \leq (1 + \varepsilon)\|A_i - A_j\|$$

for some small $\varepsilon > 0$

Assume norms are all Euclidean

Losing dimensions = “projection”

In the plane, hopeless

In 3D: no better

Recall the JLL

Thm.

Given $A \subseteq \mathbb{R}^m$ with $|A| = n$ and $\varepsilon > 0$ there is $k = O(\frac{1}{\varepsilon^2} \ln n)$ and a $k \times m$ matrix T s.t.

$$\forall x, y \in A \quad (1 - \varepsilon)\|x - y\| \leq \|Tx - Ty\| \leq (1 + \varepsilon)\|x - y\|$$

Approximate congruence: proof sketch

Thm.

①

Let T be a $k \times m$ RP sampled from $N(0, \frac{1}{k})$, and $u \in \mathbb{R}^m$ s.t. $\|u\| = 1$. Then $\mathbb{E}(\|Tu\|^2) = \|u\|^2$

RPs preserve norms on average

Thm.

Let T be a $k \times m$ rectangular matrix with each component sampled from $\mathcal{N}(0, \frac{1}{\sqrt{k}})$, and $u \in \mathbb{R}^m$ s.t. $\|u\| = 1$. Then $\mathbb{E}(\|Tu\|^2) = 1$

Proof

- ▶ Let $v = Tu$, i.e. $\forall i \leq k$ let $v_i = \sum_{j \leq m} T_{ij}u_j$
- ▶ $\mathbb{E}(v_i) = \mathbb{E}\left(\sum_{j \leq m} T_{ij}u_j\right) = \sum_{j \leq m} \mathbb{E}(T_{ij})u_j = 0$
- ▶ $\text{Var}(v_i) = \sum_{j \leq m} \text{Var}(T_{ij}u_j) = \sum_{j \leq m} \text{Var}(T_{ij})u_j^2 = \sum_{j \leq m} \frac{u_j^2}{k} = \frac{1}{k}\|u\|^2 = \frac{1}{k}$
- ▶ $\frac{1}{k} = \text{Var}(v_i) = \mathbb{E}(v_i^2 - (\mathbb{E}(v_i))^2) = \mathbb{E}(v_i^2 - 0) = \mathbb{E}(v_i^2)$
- ▶ $\mathbb{E}(\|Tu\|^2) = \mathbb{E}(\|v\|^2) = \mathbb{E}\left(\sum_{i \leq k} v_i^2\right) = \sum_{i \leq k} \mathbb{E}(v_i^2) = \sum_{i \leq k} \frac{1}{k} = 1$

Can we argue that the variance decreases wahp?

Surface area of a slice of hypersphere

$\bar{S}_m(r)$: surface of m -dimensional sphere of radius r

$$\bar{S}_m(r) = \frac{2\pi^{m/2}r^{m-1}}{\Gamma(m/2)} \quad S_m \triangleq \bar{S}_m(1)$$

Lateral surface of infinitesimally high hypercylinder

$$d\bar{S}_m(\sqrt{1-t^2}) = S_{m-1}(1-t^2)^{\frac{m-2}{2}} dt$$

Area of polar caps

$$\mathcal{A}^{\text{PC}} = 2 \int_t^1 d\bar{S}_m(s) = 2S_{m-1} \int_t^1 (1-s^2)^{\frac{m-2}{2}} ds$$

$$1+x \leq e^x \text{ for all } x \quad \text{and} \quad \int_t^1 f(s) ds \leq \int_t^\infty f(s) ds \text{ for } f \geq 0$$

$$\Rightarrow \mathcal{A}^{\text{PC}} \leq 2S_{m-1} \int_t^\infty e^{-\frac{m-2}{2}s^2} ds = \frac{2S_{m-1}}{\sqrt{m-2}} \sqrt{\frac{\pi}{2}} \operatorname{erfc}\left(\frac{\sqrt{m-2}t}{\sqrt{2}}\right) \approx O(e^{-t^2})$$

- ▶ Polar caps area decreases as $m \rightarrow \infty$ with t fixed
- ▶ Concentration of measure of the equatorial band

An intuitive explanation

- ▶ Polar caps area $\mu(\mathcal{A}_t^m) = \mu(\{u \in \mathbb{S}^{m-1} \mid |u_m| > t\})$ decreases with t fixed as $m \rightarrow \infty \Rightarrow$ **area of equatorial band $\bar{\mathcal{A}}_t^m$ increases with same conditions**
- ▶ $T\bar{\mathcal{A}}_t^m = \{u \in \mathbb{S}^{m-1} \mid ||Tu||^2 - 1| \leq t\}$ has concentration of measure (if T is stereographic)

Intermezzo: The union bound

- ▶ Events E_1, \dots, E_k such that $\mathbf{P}(E_i) \geq 1 - p$ for each $i \leq k$
- ▶ What is $\mathbf{P}(\text{all } E_i)$?
- ▶ $\mathbf{P}(\text{all } E_i) = 1 - \mathbf{P}(\text{at least one } \neg E_i) \Rightarrow$

$$\begin{aligned} \mathbf{P}\left(\bigwedge_{i \leq k} E_i\right) &= 1 - \mathbf{P}\left(\bigvee_{i \leq k} (\neg E_i)\right) \geq \\ &\geq 1 - \sum_{i=1}^k \mathbf{P}(\neg E_i) \geq 1 - \sum_{i=1}^k (1 - (1 - p)) = 1 - kp \end{aligned}$$

- ▶ So $\mathbf{P}(\text{all } E_i) \geq 1 - kp$

A syntactical explanation for $k = O(\varepsilon^{-2} \ln n)$

- ▶ $B =$ set of unit vectors; by “intuitive explanation”
 $\Rightarrow \forall u \in B \exists C > 0$ s.t. $\mathbf{P}(1 - t \leq \|Tu\| \leq 1 + t) \geq 1 - e^{-Ct^2}$
- ▶ By union bound:
 $\Rightarrow \mathbf{P}(\forall u \in B 1 - t \leq \|Tu\| \leq 1 + t) \geq 1 - |B|e^{-Ct^2}$
- ▶ Prob. $\in [0, 1] \Rightarrow$ require $1 - |B|e^{-Ct^2} > 0$:
 $\Rightarrow |B|e^{-Ct^2} < 1$
- ▶ (arbitrarily) Let $t = \varepsilon\sqrt{k}$:
 $\Rightarrow |B|e^{-C\varepsilon^2 k} < 1$
- ▶ \Rightarrow $k > C\varepsilon^{-2} \ln(|B|)$

Apply to vector differences

- ▶ Let $A \subset \mathbb{R}^m$, $|A| = n$
- ▶ $\forall x, y \in A$ we have

$$\|Tx - Ty\|^2 = \|T(x-y)\|^2 = \|x-y\|^2 \left\| T \frac{x-y}{\|x-y\|} \right\|^2 = \|x-y\|^2 \|Tu\|^2$$

where $\|u\|_2 = 1$

- ▶ $\mathbb{E}(\|Tu\|^2) = \|u\| = 1 \Rightarrow \boxed{\mathbb{E}(\|Tx - Ty\|^2) = \|x - y\|^2}$
- ▶ Let $B = \left\{ \frac{x-y}{\|x-y\|} \mid x, y \in A \right\}$
 $|B| = O(n^2) \Rightarrow k = C\varepsilon^{-2} \ln(n)$ for some constant C
- ▶ By concentration of measure on $T\bar{\mathcal{A}}^m$, $\exists \varepsilon \in (0, 1)$ s.t.

$$(1 - \varepsilon)\|x - y\|^2 \leq \|Tx - Ty\|^2 \leq (1 + \varepsilon)\|x - y\|^2 \quad (*)$$

holds with positive probability

- ▶ **Probabilistic method:** $\exists T$ such that $(*)$ holds
 \Rightarrow JLL follows

Randomized algorithm

- ▶ Distortion has low probability [Gupta 02]:

$$\forall x, y \in A \quad \mathbf{P}(\|Tx - Ty\| \leq (1 - \varepsilon)\|x - y\|) \leq 1/n^2$$

$$\forall x, y \in A \quad \mathbf{P}(\|Tx - Ty\| \geq (1 + \varepsilon)\|x - y\|) \leq 1/n^2$$

- ▶ Probability \exists pair $x, y \in A$ distorting Euclidean distance:
union bound over $\binom{n}{2}$ pairs

$$\mathbf{P}(\neg(A \text{ and } TA \text{ have almost the same shape})) \leq \binom{n}{2} \frac{2}{n^2} = 1 - \frac{1}{n}$$
$$\mathbf{P}(A \text{ and } TA \text{ have almost the same shape}) \geq 1/n$$

- ▶ Algorithm:

- ▶ $\mathbf{P}(\exists x, y \in A \text{ with large JLL discrepancy}) \leq 1 - 1/n$
- ▶ Consider $t > 1$ independent samplings of random RP T
- ▶ Probability that all have large discrepancy: $\leq (1 - 1/n)^t$
- ▶ Choose t so at least one T will be good with prob. ≥ 0.99 :
 $(1 - 1/n)^t \leq 1 - 0.99 = 0.01$ yields $t \geq \ln(0.01)/\ln(1 - 1/n)$
if $n = 100$, get $t \geq 459$

Subsection 2

Projecting LP feasibility

Pure feasibility LP: easy cases

Thm.

$T : \mathbb{R}^m \rightarrow \mathbb{R}^k$ a RP, and $b, A_1, \dots, A_n \in \mathbb{R}^m$. For any given vector $x \in X$, we have:

(i) If $b = \sum_{i=1}^n x_i A_i$ then $Tb = \sum_{i=1}^n x_i T A_i$
by linearity of T

(ii) If $b \neq \sum_{i=1}^n x_i A_i$ then $\mathbf{P}\left(Tb \neq \sum_{i=1}^n x_i T A_i\right) \geq 1 - 2e^{-Ck}$
by JLL applied to $\|b - \sum_i x_i A_i\|$

(iii) If $b \neq \sum_{i=1}^n y_i A_i$ for all $y \in X \subseteq \mathbb{R}^n$, where $|X|$ is finite, then

$$\mathbf{P}\left(\forall y \in X \quad Tb \neq \sum_{i=1}^n y_i T A_i\right) \geq 1 - 2|X|e^{-Ck}$$

for some constant $C > 0$ (independent of n, k)
by union bound

Separating hyperplanes

When $|X|$ is large, project separating hyperplanes instead

- ▶ **Convex $C \subseteq \mathbb{R}^m$, $x \notin C$:**
then \exists hyperplane c separating x from C
- ▶ In particular, true if $C = \text{cone}(A_1, \dots, A_n)$ for $A \subseteq \mathbb{R}^m$
- ▶ **Can show $x \in C \Leftrightarrow Tx \in TC$ with high probability**
- ▶ As above, if $x \in C$ then $Tx \in TC$ by linearity of T
Difficult part is proving the converse
- ▶ Can also project point-to-cone distances

Projection of separating hyperplanes

Thm.

Given $c, b, A_1, \dots, A_n \in \mathbb{R}^m$ of unit norm s.t. $b \notin \text{cone}\{A_1, \dots, A_n\}$ pointed, $\varepsilon > 0$, $c \in \mathbb{R}^m$ s.t. $c^\top b < -\varepsilon$, $c^\top A_i \geq \varepsilon$ ($i \leq n$), and T a RP:

$$\mathbf{P}[Tb \notin \text{cone}\{TA_1, \dots, TA_n\}] \geq 1 - 4(n+1)e^{-\mathcal{C}(\varepsilon^2 - \varepsilon^3)k}$$

for some constant \mathcal{C} .

Proof

Let \mathcal{A} be the event that T approximately preserves $\|c - \chi\|^2$ and $\|c + \chi\|^2$ for all $\chi \in \{b, A_1, \dots, A_n\}$. Since \mathcal{A} consists of $2(n+1)$ events, by the JLL (“squared variant”) and the union bound, we get

$$\mathbf{P}(\mathcal{A}) \geq 1 - 4(n+1)e^{-\mathcal{C}(\varepsilon^2 - \varepsilon^3)k}$$

Now consider $\chi = b$

$$\langle Tc, Tb \rangle = \frac{1}{4}(\|T(c+b)\|^2 - \|T(c-b)\|^2)$$

$$\begin{aligned} \text{by JLL} \quad &\leq \frac{1}{4}(\|c+b\|^2 - \|c-b\|^2) + \frac{\varepsilon}{4}(\|c+b\|^2 + \|c-b\|^2) \\ &= c^\top b + \varepsilon < 0 \end{aligned}$$

and similarly $\langle Tc, TA_i \rangle \geq 0$

[Vu et al., Math. OR, 2018]

The feasibility projection theorem

Thm.

Given $\delta > 0$, \exists sufficiently large $m \leq n$ such that:

for any LFP input A, b where A is $m \times n$

we can sample a random $k \times m$ matrix T with $k \ll m$

and

$$\mathbf{P}(\text{orig. LFP feasible} \iff \text{proj. LFP feasible}) \geq 1 - \delta$$

Subsection 3

Projecting LP optimality

Notation

- ▶ $P \equiv \min\{cx \mid Ax = b \wedge x \geq 0\}$ (*original problem*)
- ▶ $TP \equiv \min\{cx \mid TAx = Tb \wedge x \geq 0\}$ (*projected problem*)
- ▶ $v(P)$ = optimal objective function value of P
- ▶ $v(TP)$ = optimal objective function value of TP

The optimality projection theorem

- ▶ Assume $\text{feas}(P)$ is bounded
- ▶ Assume all optima of P satisfy $\sum_j x_j \leq \theta$ for some given $\theta > 0$
(prevents unboundedness)

Thm.

Given $\gamma > 0$,

$$v(P) - \gamma \leq v(TP) \leq v(P) \quad (*)$$

holds with arbitrarily high probability (w.a.h.p.)

more precisely, (*) holds with prob. $1 - 4ne^{-C(\varepsilon^2 - \varepsilon^3)k}$ where $\varepsilon = \gamma / (2(\theta + 1)\eta)$ and $\eta = O(\|y\|_2)$ where y is a dual optimal solution of P having minimum norm

The easy part

Show $v(TP) \leq v(P)$:

- ▶ Constraints of P : $Ax = b \wedge x \geq 0$
- ▶ Constraints of TP : $TAx = Tb \wedge x \geq 0$
- ▶ \Rightarrow constraints of TP are lin. comb. of constraints of P
- ▶ \Rightarrow any solution of P is feasible in TP
(btw, the converse holds almost never)
- ▶ P and TP have the same objective function
- ▶ $\Rightarrow TP$ is a **relaxation** of $P \Rightarrow v(TP) \leq v(P)$

The hard part (sketch)

- ▶ Eq. (12) equivalent to P for $\gamma = 0$

$$\left. \begin{array}{l} cx \leq v(P) - \gamma \\ Ax = b \\ x \geq 0 \end{array} \right\} \quad (12)$$

Note: for $\gamma > 0$, Eq. (12) is infeasible

- ▶ By feasibility projection theorem,

$$\left. \begin{array}{l} cx \leq v(P) - \gamma \\ TA x = Tb \\ x \geq 0 \end{array} \right\}$$

is infeasible w.a.h.p. for $\gamma > 0$

- ▶ Re-state: $cx < v(P) - \gamma \wedge TA x = Tb \wedge x \geq 0$ infeasible w.a.h.p.
- ▶ $\Rightarrow cx \geq v(P) - \gamma$ holds w.a.h.p. for $x \in \text{feas}(TP)$
- ▶ $\Rightarrow v(P) - \gamma \leq v(TP)$

Subsection 4

Solution retrieval

Projected solutions are infeasible in P

▶ $Ax = b \Rightarrow TAx = Tb$ by linearity

▶ However,
Thm.

For $x \geq 0$ s.t. $TAx = Tb$, $Ax = b$ with probability zero

if not, an x belonging to $(n - k)$ -dim. subspace would belong to an $(n - m)$ -dim. subspace (with $k \ll m$) with positive probability

▶ Can't get solution for original LFP using projected LFP!

Solution retrieval by duality

- ▶ Primal $\min\{c^\top x \mid Ax = b \wedge x \geq 0\} \Rightarrow$
dual $\max\{b^\top y \mid A^\top y \leq c\}$
- ▶ Let $x' = \text{sol}(TP)$ and $y' = \text{sol}(\text{dual}(TP))$
- ▶ $\Rightarrow (TA)^\top y' = (A^\top T^\top)y' = A^\top (T^\top y') \leq c$
- ▶ $\Rightarrow T^\top y'$ is a solution of $\text{dual}(P)$
- ▶ \Rightarrow we can compute an **optimal basis** J for P
- ▶ Solve $A_J x_J = b$, get x_J , obtain a solution x^* of P
- ▶ *Won't work in practice: errors in computing J*

Solution retrieval by projected basis

- ▶ H : optimal basis of TP
we can trust that — given by solver
- ▶ $|H| = k \Rightarrow A_H$ is $m \times k$ (tall and slim)
- ▶ **Pseudoinverse**: solve $k \times k$ system $A_H^\top A_H x_H = A_H^\top b$
 $\Rightarrow x_H = (A_H^\top A_H)^{-1} A_H^\top b$
- ▶ let $x = (x_H, 0)$
- ▶ *Can prove small feasibility error waph*
- ▶ **ISSUE**: may be slightly infeasible
empirically: $x \not\geq 0$ but $x^- = \min(0, x) \rightarrow 0$ as $k \rightarrow \infty$

Project idea 5: Test the output of duality and projected basis retrieval methods on a set of 50 random large feasible standard-form LPs: you should find that the duality method is worse than the projected basis method. Formulate a reasoned hypothesis about the reason why this happens

Projected LP duals

- ▶ The dual of $P \equiv \min\{cx \mid Ax = b \wedge x \geq 0\}$ is
 $D \equiv \max\{yb \mid yA \leq c\}$
- ▶ A projected dual on $y \in \mathbb{R}^m$ can be derived as follows:
 $\max\{(yT^\top)Tb \mid (yT^\top)TA \leq c\}$
- ▶ Replacing $u = yT^\top \in \mathbb{R}^k$, we obtain
 $TD \equiv \max\{u\bar{b} \mid u\bar{A} \leq c\}$ where $\bar{b} = Tb$, $\bar{A} = TA$
- ▶ Theory [D'Ambrosio et al. *MPB* 2020]:
 - ▶ if original dual is feasible, projected dual is feasible
 - ▶ approximation guarantees on projected dual objective function
 - ▶ retrieval: if $\bar{u} \in \arg \text{opt}(TD)$, let $\tilde{y} = \bar{u}T$, \tilde{y} is feasible in D

Project idea 6: Develop an algorithm for finding a candidate solution x' of P from \tilde{y} . Sample 50 random large standard form LP instances, solve P , TP , TD for each instance. Collect soln. x^* from P , \tilde{x} from TP , x' from TD , then compute objective function value and feasibility error w.r.t. P of x^* , \tilde{x} , x' . Plot all this data in function of the number of rows of A and ε

Subsection 5

Application to quantile regression

Conditional random variables

- ▶ random variable B conditional on A_1, \dots, A_p
- ▶ assume B depends linearly on $\{A_j \mid j \leq p\}$
- ▶ want to find $x_1, \dots, x_n \in \mathbb{R}$ s.t.

$$B = \sum_{j \leq p} x_j A_j$$

- ▶ use samples $b, a_1, \dots, a_p \in \mathbb{R}^m$ to find estimates
- ▶ $a^i = \text{row}$, $a_j = \text{column}$

Sample statistics

- ▶ expectation:

$$\hat{\mu} = \arg \min_{\mu \in \mathbb{R}} \sum_{i \leq m} (b_i - \boxed{\mu})^2$$

- ▶ conditional expectation (*linear regression*):

$$\hat{\nu} = \arg \min_{\nu \in \mathbb{R}^p} \sum_{i \leq m} (b_i - \boxed{\nu a^i})^2$$

- ▶ sample median:

$$\begin{aligned} \hat{\xi} &= \arg \min_{\xi \in \mathbb{R}} \sum_{i \leq m} |b_i - \xi| \\ &= \arg \min_{\xi \in \mathbb{R}} \sum_{i \leq m} \left(\frac{1}{2} \max(b_i - \xi, 0) - \frac{1}{2} \min(b_i - \xi, 0) \right) \end{aligned}$$

- ▶ conditional sample median: *similarly*

Quantile regression

- ▶ sample τ -quantile:

$$\hat{\xi} = \arg \min_{\xi \in \mathbb{R}} \sum_{i \leq m} (\tau \max(b_i - \xi, 0) - (1 - \tau) \min(b_i - \xi, 0))$$

- ▶ conditional sample τ -quantile (*quantile regression*):

$$\hat{\beta} = \arg \min_{\beta \in \mathbb{R}^p} \sum_{i \leq m} (\tau \max(b_i - \beta a^i, 0) - (1 - \tau) \min(b_i - \beta a^i, 0))$$

Linear Programming formulation

Let $A = (a_j \mid j \leq n)$; then

$$\hat{\beta} = \arg \min \left. \begin{array}{l} \tau u^+ + (1 - \tau)u^- \\ A(\beta^+ - \beta^-) + u^+ - u^- = b \\ \beta, u \geq 0 \end{array} \right\}$$

- ▶ **parameters:** A is $m \times p$, $b \in \mathbb{R}^m$, $\tau \in \mathbb{R}$
- ▶ **decision variables:** $\beta^+, \beta^- \in \mathbb{R}^p$, $u^+, u^- \in \mathbb{R}^m$
- ▶ LP constraint matrix is $m \times (2p + 2m)$
density: $p/(p + m)$ — can be high

Project idea 7: Test the application of RPs on at 50 large random MULTICOMMODITY FLOW (MCF) problems. Plot the ratio of projected to original objective, retrieved to original objective, and infeasibility errors in function of the number of rows of the equality system $Ax = b$ and ε . Is MCF a good application testbed for RP?

Large datasets

- ▶ Russia Longitudinal Monitoring Survey `hh1995f`
 - ▶ $m = 3783, p = 855$
 - ▶ $A = \text{hh1995f}, b = \log \text{avg}(A)$
 - ▶ 18.5% dense
 - ▶ poorly scaled data, CPLEX yields infeasible (!!!) after around 70s CPU
 - ▶ `quantreg` in R fails
- ▶ 14596 RGB photos on my HD, scaled to 90×90 pixels
 - ▶ $m = 14596, p = 24300$
 - ▶ each row of A is an image vector, $b = \sum A$
 - ▶ 62.4% dense
 - ▶ CPLEX killed by OS after ≈ 30 min (presumably for lack of RAM) on 16GB
 - ▶ could not load dataset in R

Electricity prices

- ▶ Every hour over 365 days in 2015 (8760 rows)
- ▶ From 22 countries (columns) from the European zone

- ▶ Permutation (18,2) (21,20) applied to proj gives same nonzero pattern and reduces ℓ_2 error from 0.13 to 0.01
- ▶ For every proj solution I found I could always find a permutation with this property!!
- ▶ ... On closer inspection, many columns reported equal data
- ▶ *Small numerical error*
- ▶ *Approximate solutions respect Nonzero pattern*
- ▶ LP too small for approximation to have an impact on CPU time

Outline

Introduction

- MP language
- Solvers
- MP systematics
- Some applications

Decidability

- Formal systems
- Gödel
- Turing
- Tarski
- Completeness and incompleteness
- MP solvability

Efficiency and Hardness

- Some combinatorial problems in NP
- NP-hardness
- Complexity of solving MP formulations

Distance Geometry

- The universal isometric embedding
- Dimension reduction
- Dealing with incomplete metrics
- The Isomap heuristic
- Distance geometry problem
- Distance geometry in MP
- DGP cones
- Barvinok's Naive Algorithm
- Isomap revisited

Summary

Random projections in LP

- Random projection theory
- Projecting LP feasibility
- Projecting LP optimality
- Solution retrieval
- Application to quantile regression

Sparsity and ℓ_1 minimization

- Motivation
- Basis pursuit
- Theoretical results
- Application to noisy channel encoding
- Improvements

Kissing Number Problem

- Lower bounds
- Upper bounds from SDP?
- Gregory's upper bound
- Delsarte's upper bound
- Pfender's upper bound

Clustering in Natural Language

- Clustering on graphs
- Clustering in Euclidean spaces
- Distance instability
- MP formulations
- Random projections again

Subsection 1

Motivation

Coding problem for costly channels

► Task:

send long sparse vector $y \in \mathbb{R}^n$ on costly channel

1. construct $m \times n$ encoding matrix A with $m \leq n$
both parties know A
2. encode $b = Ay \in \mathbb{R}^m$
3. send b

► Decode by finding sparsest x s.t. $Ax = b$

can we expect $x \approx y$, i.e. small $\|x - y\|$?

► Summary:

1. given long sparse vector y
2. shorten it to b , send b
3. upon receiving b , recover long sparse vector y

Coding problem for noisy channels

- ▶ **Task:** send vector $w \in \mathbb{R}^d$ on a noisy channel
- ▶ **Encoding:** $n \times d$ matrix Q with $n > d$, send $z = Qw \in \mathbb{R}^n$
both parties know Q
- ▶ **Error prob. e :** en components of z sent wrong
- ▶ **Receive (wrong) vector $\bar{z} = z + x$ where x is sparse**
- ▶ **Can we recover z ?**

- ▶ Choose $m \times n$ matrix A s.t. $m = n - d$ and $AQ = 0$
 - ▶ Let $b = A\bar{z} = A(z + x) = A(Qw + x) = AQw + Ax = Ax$
 - ▶ Suppose we can find sparsest x' s.t. $Ax' = b$
 - ▶ \Rightarrow we can recover $z' = \bar{z} - x'$
- ▶ Recover $w' = (Q^T Q)^{-1} Q^T z'$ (pseudoinverse)
What is the likelihood of getting small $\|w - w'\|$?

Summary: 1. given **short dense** vector w , 2. **lengthen** it to z for redundancy; 3. send z and receive $\bar{z} = z + x$; 4. find **long sparse** error vector x using **short** vector $b = A\bar{z}$; 5. recover z' then w'

What these tasks have in common

- ▶ Given matrix A with fewer rows than columns
- ▶ Given vector b
- ▶ Find sparsest solution x^* of $Ax = b$
- ▶ Note: $Ax = b$ feasible iff $\text{rank}(A) = \text{rank}(A|b)$

Subsection 2

Basis pursuit

Sparsest solution of a linear system

- ▶ Problem $P^0(A, b) \equiv \min\{\|x\|_0 \mid Ax = b\}$ is **NP-hard**
Reduction from EXACT COVER BY 3-SETS [Garey&Johnson 1979, A6[MP5]]
MILP: $\min\{\sum_j y_j \mid \forall j -My_j \leq x_j \leq My_j \wedge Ax = b \wedge y \in \{0, 1\}^n\}$

- ▶ $P^1(A, b) \equiv \min\{\|x\|_1 \mid Ax = b\}$
is a relaxation

- ▶ Reformulate to LP:

$$\left. \begin{array}{ll} \min & \sum_{j \leq n} s_j \\ \forall j \leq n & -s_j \leq x_j \leq s_j \\ & Ax = b \end{array} \right\} \quad (\dagger)$$

- ▶ Empirical observation: P^1 often finds optimum of P^0
Too often for this to be a coincidence
- ▶ Theoretical justification by Candès, Tao, Donoho
Mathematics of sparsity, Compressed sensing, Compressive sampling
- ▶ Note: we always assume $b \neq 0$ in $P^0(A, b)$ and $P^1(A, b)$

Graphical intuition 1

- ▶ Wouldn't work with ℓ_2, ℓ_∞ norms

$Ax = b$ flat at poles — “zero probability of sparse solution”

Warning: *this is not a proof, and \exists cases not explained by this drawing* [Candès 2014]

Graphical intuition 2

- ▶ \hat{x} such that $A\hat{x} = b$ approximates x in ℓ_p norms
- ▶ $p = 1$ only convex case zeroing some components

From [Davenport et al., 2012]; again, this is not a proof!

Phase transition in sparse recovery

For $x \in \mathbb{R}^n$, $A \in \mathbb{R}^{m \times n}$: consider $P^1(A, Ax)$ and its opt. x^*

Pixel grayscale: avg density of x^* over many samplings of A ; white = sparse, black = dense

$\text{Prob}(x^* \text{ has sparsity } s)$ undergoes a phase transition

For a given n , if m is too small P^1 fails to find the optimum of P^0

[Tropp et al., Information and Inference, 2014]

Subsection 3

Theoretical results

Main theorem and proof structure

Defn. (i) Given a small $\epsilon \geq 0$, a scalar α is *near-zero* if $|\alpha| < \epsilon$;
(ii) a vector is *s-sparse* if it has $\leq s$ nonzero components

► **Thm.** Let:

1. $A \sim N(0, 1)^{mn}$ with $m < n$ but m “not too small”
2. $\hat{x} \in \mathbb{R}^n$ have s nonzeros and $n - s$ zeros or near-zeros
3. \bar{x} be the best approx of \hat{x} with exactly s nonzeros
4. $\hat{b} = A\hat{x}$ and x^* be the unique s -sparse min of $P^1(A, \hat{b})$

then x^* is a “good approximation” of \bar{x} (★)

► **Proof sketch:**

- **Prop.** A has the null space property (NSP) \Rightarrow (★)
- **Prop.** A has restricted isometry prop. (RIP) $\Rightarrow A$ has NSP
- **Prop.** $A \sim N(0, 1)^{mn} \Rightarrow A$ has RIP
- adapt to near-zeros by modifying NSP

Some notation

Defn. (i) For any $n \in \mathbb{N}$ define $[n] = \{1, \dots, n\}$;
(ii) for $z \in \mathbb{R}^n$ and $S \subseteq [n]$ let $z[S] = ((z_j \text{ iff } j \in S) \text{ xor } 0 \mid j \leq n)$ be the *restriction* of z to S

- ▶ Consider $Ax = b$ where A is $m \times n$ with $m < n$
 \Rightarrow *if feasible it has uncountably many solutions*
- ▶ Let $x \in \mathbb{R}^n$ s.t. $Ax = b$, $\mathbf{N}_A = \text{null}(A)$, $\mathbf{N}_A^0 = \mathbf{N}_A \setminus \{0\}$
 $\Rightarrow \forall y \in \mathbf{N}_A$ we have $A(x + y) = Ax + Ay = Ax + 0 = b$
- ▶ For $S \subseteq [n]$ let $\bar{S} = [n] \setminus S$
- ▶ Note that $\forall z \in \mathbb{R}^n$ we have $z = z[S] + z[\bar{S}]$

Null space property

Defn. For $x \in \mathbb{R}^n$ let $\text{supp}(x) = \{j \leq n \mid x_j \neq 0\}$

► **Defn.** $\text{NSP}_s(A) \equiv$

$$\forall S \subseteq [n] (|S| = s \rightarrow \forall y \in \mathbf{N}_A^0 \quad \|y[S]\|_1 < \|y[\bar{S}]\|_1)$$

A has the null space property of order s

► We show that *A has the NSP of order s* is the same as stating that *$Ax = b$ has an s-sparse solution that is the unique optimum of $P^1(A, b)$*

► **Prop.** $\forall x^* \in \mathbb{R}^n$ with $|\text{supp}(x^*)| \leq s$
 $[x^* \text{ unique min of } P^1(A, Ax^*)] \Leftrightarrow \text{NSP}_s(A)$

the “NSP proposition”

Strength of NSP_t as t grows

NSP Prop. states $|\text{supp}(x^)| \leq s$ but $\text{NSP}_s(A)$ assumes $|S| = s$: why?*

Lemma

$$\forall A \in \mathbb{R}^{m \times n}, t < s \leq n \quad \text{NSP}_s(A) \Rightarrow \text{NSP}_t(A)$$

Proof

$\text{NSP}_s(A) \equiv \forall S \subseteq [n] (|S| = s \rightarrow \forall y \in \mathbf{N}_A^0 \|y[S]\|_1 < \|y[\bar{S}]\|_1)$, hence:
given $T, U \subseteq [n]$ with T, U nontrivial disjoint, $|T| = t$ and $|T \cup U| = s$,

$$\bullet \quad \forall y \in \mathbf{N}_A^0 \quad \|y[T \cup U]\|_1 < \|y[\overline{T \cup U}]\|_1 = \|y[[n] \setminus (T \cup U)]\|_1 \Rightarrow$$

$$(\dagger) \quad \forall y \in \mathbf{N}_A^0 \quad \|y[T]\|_1 + \|y[U]\|_1 < \|y\|_1 - \|y[T]\|_1 - \|y[U]\|_1 \Rightarrow$$

$$(\ddagger) \quad \forall y \in \mathbf{N}_A^0 \quad \|y[T]\|_1 < \|y[\bar{T}]\|_1 - 2\|y[U]\|_1$$

$$\bullet \quad \text{whence } \forall T \subseteq [n] (|T| = t \rightarrow \forall y \in \mathbf{N}_A^0 \|y[T]\|_1 < \|y[\bar{T}]\|_1)$$

since $\|y[U]\|_1 > 0$, and so $\text{NSP}_t(A)$

$$(\dagger) \quad \|y[T \cup U]\|_1 = \sum_{j \in T \cup U} |y_j| = \sum_{j \in T} |y_j| + \sum_{j \in U} |y_j| = \|y[T]\|_1 + \|y[U]\|_1$$

$$\|y[[n] \setminus V]\|_1 = \sum_{j \in [n] \setminus V} |y_j| = \sum_{j \in [n]} |y_j| - \sum_{j \in V} |y_j| = \|y\|_1 - \|y[V]\|_1$$

$$(\ddagger) \quad \|y\|_1 - \|y[T]\|_1 = \sum_{j \leq n} |y_j| - \sum_{j \in T} |y_j| = \sum_{j \notin T} |y_j| = \sum_{j \in \bar{T}} |y_j| = \|y[\bar{T}]\|_1$$

Proof of the NSP proposition (\Rightarrow)

$\forall x^* (|\text{supp}(x^*)| = s \rightarrow x^* \text{ uniq min } P^1(A, Ax^*)) \Rightarrow \text{NSP}_s(A)$

► Claim $\forall y \in \mathbf{N}_A^0$ and $S \subseteq [n]$ with $|S| = s$ we have $Ay[S] \neq 0$

Pf. $y[S]$ has $|\text{supp}(x)| = s$, by hyp $y[S]$ uniq min of $P^1(A, Ay[S])$; if $Ay[S] = 0$ then $\mathbf{0}$ solves $P^1(A, Ay[S])$ and $\|\mathbf{0}\|_1 < \|y[S]\|_1$ contradicting min, so $Ay[S] \neq 0$

► $\forall y \in \mathbb{R}^n$ and $S \subseteq [n]$ we have $y = y[S] + y[\bar{S}]$

► \Rightarrow for any $y \in \mathbf{N}_A^0$ we have $Ay = Ay[S] + Ay[\bar{S}] = 0$
 $\Rightarrow A(-y[\bar{S}]) = Ay[S] \neq 0$ by claim

► Therefore, $-y[\bar{S}]$ is feasible in $P^1(A, Ay[S])$

► $y[S] \neq -y[\bar{S}]$ othw by $y = y[S] + y[\bar{S}]$ both would be scalings of y and hence both in \mathbf{N}_A^0 , which cannot happen as $Ay[S] \neq 0$

► $\|y[S]\|_1$ uniq min value and $-y[\bar{S}]$ feas in $P^1(A, Ay[S]) \Rightarrow$
 $\| -y[\bar{S}]\|_1 = \|y[\bar{S}]\|_1 > \|y[S]\|_1 \Rightarrow \text{NSP}_s(A)$

Proof of the NSP proposition (\Leftarrow)

NSP_s(A) $\Rightarrow \forall x^*$ ($|\text{supp}(x^*)| = s \rightarrow x^*$ uniq min $P^1(A, Ax^*)$)

- ▶ Let $x^* \in \mathbb{R}^n$, $b = Ax^*$, $S = \text{supp}(x^*)$ and $|S| = s$
- ▶ Let \bar{x} soln. of $Ax = b$, then $\bar{x} = x^* - y$ with $y \in N_A^0$

$$\begin{aligned} \text{[add and subtract same qty]} \quad \|x^*\|_1 &= \|(x^* - \bar{x}[S]) + \bar{x}[S]\|_1 \\ &\text{[by triangle inequality]} \leq \|x^* - \bar{x}[S]\|_1 + \|\bar{x}[S]\|_1 \\ [S = \text{supp}(x^*) \Rightarrow x^* = x^*[S]] &= \|x^*[S] - \bar{x}[S]\|_1 + \|\bar{x}[S]\|_1 \\ &\text{[since } x^* - \bar{x} = y] = \|y[S]\|_1 + \|\bar{x}[S]\|_1 \\ \text{[since } y \in N_A^0 \text{ and NSP}_s(A) \text{ holds]} &< \|y[\bar{S}]\|_1 + \|\bar{x}[S]\|_1 \\ &\text{[since } y = x^* - \bar{x} \text{ and } x^*[\bar{S}] = 0] = \|- \bar{x}[\bar{S}]\|_1 + \|\bar{x}[S]\|_1 \\ \text{[since } \|-z\|_1 = \|z\|_1 \wedge z[S] + z[\bar{S}] = z] &= \|\bar{x}\|_1 \\ &\Rightarrow \|x^*\|_1 < \|\bar{x}\|_1 \end{aligned}$$

so x^* is a min of $P^1(A, Ax^*)$; ℓ_1 norm strictly convex $\Rightarrow x^*$ uniq min

A variant of the null space property

► **Motivation: “almost sparse solutions”**

given \hat{x} with $|\text{supp}(\hat{x})| > s$ and $b = A\hat{x}$

let $S = \arg \max_{T \subseteq [n]: |T|=s} \|\hat{x}[T]\|_1$ and $\bar{x} = \hat{x}[S]$ ($\Rightarrow |\text{supp}(\bar{x})| = s$)

► Assume $\|\hat{x}[\bar{S}]\|_1 \ll \|\hat{x}[S]\|_1$ and $\epsilon = \max_{j \in \bar{S}} |\hat{x}_j|$ is small

i.e. \hat{x} “almost” has support size s (up to ϵ)

► Show $\min x^*$ of $P^1(A, A\hat{x})$ is s -sparse and close to \hat{x}

► Generalize NSP with $\rho \in (0, 1)$: $\text{NSP}_s^\rho(A) \Leftrightarrow$

$$\boxed{\forall S \subseteq [n] (|S| = s \rightarrow \forall y \in \mathbf{N}_A^0 \|y[S]\|_1 \leq \rho \|y[\bar{S}]\|_1)}$$

► **Prop.** $\text{NSP}_s^\rho(A) \Rightarrow$ if x^* min of $P^1(A, A\hat{x})$ then

$$\|x^* - \hat{x}\|_1 \leq 2 \frac{1+\rho}{1-\rho} \|\bar{x} - \hat{x}\|_1 \leq (n-s)\epsilon$$

i.e. x^ is a good approximation of \bar{x}*

► Moreover, if $|\text{supp}(\hat{x})| = s$ then $x^* = \hat{x} = \bar{x}$

Proof of the NSP_s^ρ proposition

- ▶ x^* feasible in $Ax = A\hat{x}$ so $\exists! y \in \mathbf{N}_A$ ($x^* = \hat{x} + y$)
- ▶ $\Rightarrow \|x^*\|_1 = \|\hat{x} + y\|_1 \leq \|\hat{x}\|_1$ since x^* min of $P^1(A, A\hat{x})$
- ▶ $\|\hat{x} + y\|_1 = \sum_{j \in S} |\hat{x}_j + y_j| + \sum_{j \in \bar{S}} |\hat{x}_j + y_j|$
 $\geq \sum_{j \in S} (|\hat{x}_j| - |y_j|) + \sum_{j \in \bar{S}} (|y_j| - |\hat{x}_j|)$ by triangle ineq
- ▶ $= \|\hat{x}[S]\|_1 - \|y[S]\|_1 + \|y[\bar{S}]\|_1 - \|\hat{x}[\bar{S}]\|_1$ (add and subtract $\|\hat{x}[\bar{S}]\|_1 \Rightarrow$)
 $= \|\hat{x}\|_1 - 2\|\hat{x}[\bar{S}]\|_1 + \|y[\bar{S}]\|_1 - \|y[S]\|_1$ (since $\bar{x} = \hat{x}[S] \Rightarrow$)
 $= \|\hat{x}\|_1 - 2\|\hat{x} - \bar{x}\|_1 + \|y[\bar{S}]\|_1 - \|y[S]\|_1$ (*)
- ▶ Therefore (*) $\leq \|\hat{x} + y\|_1 \leq \|\hat{x}\|_1$ since x^* opt of $P^1(A, A\hat{x})$ whence
 $\|\hat{x}\|_1 \geq \|\hat{x}\|_1 - 2\|\hat{x} - \bar{x}\|_1 + \|y[\bar{S}]\|_1 - \|y[S]\|_1$ (cancel $\|\hat{x}\|_1 \Rightarrow$)
 $2\|\hat{x} - \bar{x}\|_1 \geq \|y[\bar{S}]\|_1 - \|y[S]\|_1$
- ▶ By NSP_s^ρ , $-\|y[S]\|_1 \geq -\rho\|y[\bar{S}]\|_1$, so
 $2\|\hat{x} - \bar{x}\|_1 \geq (1 - \rho)\|y[\bar{S}]\|_1$ whence $\|y[\bar{S}]\|_1 \leq \frac{2}{1-\rho}\|\hat{x} - \bar{x}\|_1$ (†)
- ▶ $x^* = \hat{x} + y \Rightarrow \|x^* - \hat{x}\|_1 = \|y\|_1 = \|y[S]\|_1 + \|y[\bar{S}]\|_1$
 by NSP_s^ρ $\|y[S]\|_1 \leq \rho\|y[\bar{S}]\|_1$ hence $\|x^* - \hat{x}\|_1 \leq (1 + \rho)\|y[\bar{S}]\|_1$
 by (†) $\|x^* - \hat{x}\|_1 \leq 2\frac{1+\rho}{1-\rho}\|\hat{x} - \bar{x}\|_1$
- ▶ Further, $\|\hat{x} - \bar{x}\|_1 = \|\hat{x} - \hat{x}[S]\|_1 = \|\hat{x}[\bar{S}]\|_1 \leq |\bar{S}|\epsilon = (n - s)\epsilon$

Restricted isometry property

► A is an $m \times n$ matrix, $\delta \in (0, 1)$, $s \in \mathbb{N}$

► $\text{RIP}_s^\delta(A) \Leftrightarrow \forall x \in \mathbb{R}^n$ s.t. $|\text{supp}(x)| = s$ we have

$$(1 - \delta) \|x\|_2^2 \leq \|Ax\|_2^2 \leq (1 + \delta) \|x\|_2^2$$

► **Prop.** $\text{RIP}_{2s}^\delta(A) \wedge \rho = \frac{\sqrt{2}\delta}{1-\delta} < 1 \Rightarrow \text{NSP}_s^\rho(A)$

See Thm. 5.12 in [Damelin & Miller 2012] for a proof

► It suffices that $\delta < \sqrt{2} - 1 \approx 0.4142$

RIP and $P^0(A, b)$

- ▶ Recall $P^0(A, b) \equiv \min\{\|x\|_0 \mid Ax = b\}$ is **NP-hard** find solution to $Ax = b$ with smallest support size
- ▶ **Thm.** Let $\hat{x} \in \mathbb{R}^n$ with $|\text{supp}(\hat{x})| = s$, $\delta < 1$, A a matrix s.t. $\text{RIP}_{2s}^\delta(A)$, $x^* = \arg P^0(A, A\hat{x})$; then $x^* = \hat{x}$

Pf. Suppose false, let $y = x^* - \hat{x} \neq 0$; by defn of x^* we have $\|x^*\|_0 \leq \|\hat{x}\|_0 \leq s$, hence $\|y\|_0 \leq 2s$; since A has RIP get $\|Ay\|_2^2 \in (1 \pm \delta)\|y\|_2^2$, but $Ay = Ax^* - A\hat{x} = 0$ while $y \neq 0$, and $\delta \in (0, 1) \rightarrow 1 \pm \delta > 0$, hence $0 \in (\alpha, \beta)$ where $\alpha, \beta > 0$, contradiction

Thm. 23.6 [Shwartz & Ben-David, 2014]

- ▶ Result of limited scope, since we don't know if $P^0(A, b)$ can be solved efficiently if A has the RIP

Sufficient eigenvalue conditions for RIP

- ▶ Recall $\text{RIP}_s^\delta(A)$: $\forall x$ with $S = \text{supp}(x)$ and $|S| = s$

$$(1 - \delta)\|x\|_2^2 \leq \|Ax\|_2^2 \leq (1 + \delta)\|x\|_2^2$$

- ▶ Let $A^J = (A^j \mid j \in J)$, where A^j is the j -th col. of A

- ▶ $\|Ax\|_2^2 = \langle Ax, Ax \rangle = \langle A^S x[S], A^S x[S] \rangle = \langle B_S x[S], x[S] \rangle$

where $B_S = (A^S)^\top A^S$ is $s \times s$ and PSD, and consider $x[S]$ as a vector in \mathbb{R}^s

- ▶ $\Rightarrow 0 \leq \lambda_{\min}(B_S)\|x\|_2^2 \leq \langle B_S x, x \rangle \leq \lambda_{\max}(B_S)\|x\|_2^2$

replace B_S by its spectral decomp $P\Lambda P^\top$, note $\Lambda = \text{diag}(\lambda_{\min}, \dots, \lambda_{\max})$

- ▶ Let $\lambda^L = \min_{|S|=s} \lambda_{\min}(B_S)$, $\lambda^U = \max_{|S|=s} \lambda_{\max}(B_S)$

- ▶ $\Leftarrow \exists \delta > 0$ s.t. $1 - \delta \leq \lambda^L \leq \lambda^U \leq 1 + \delta$

i.e. all eigenvalues of $B(S)$ close to 1 for all $S \subset [n]$ with $|S| = s$

Construction of A s.t. $\text{RIP}_s^\delta(A)$

- ▶ Need $\lambda \approx 1$ for each eigenvalue λ of B_S
- ▶ \Rightarrow Need $\forall S \subseteq N \quad |S| = s \rightarrow (A^S)^\top A^S \approx I_s$
- ▶ \Rightarrow Need

$$\begin{aligned} \forall i < j \leq n \quad (A^i)^\top A^j &\approx 0 \\ \forall i \leq n \quad (A^i)^\top A^i = \|A^i\|_2^2 &\approx 1 \end{aligned}$$

- ▶ **Sufficient condition:** A sampled from $\mathbf{N}(0, \frac{1}{\sqrt{m}})$ ^{mn}
- ▶ *Difference with JLL*
RIP holds for uncountably many vectors x with $|\text{supp}(x)| = s$
JLL holds for given sets of finitely many vectors with any support

Project idea 8: What other types of rectangular matrices M have the property $M^\top M = I$ or $\approx I$? Can they be used to prove the main theorem? How do they work, computationally, compared with matrices sampled from normal distributions? Compare on at least 50 random instances of $P^1(A, b)$

Isotropic vectors

1. **Defn.** Rnd vect $a \in \mathbb{R}^m$ is *isotropic* iff $\text{cov}(a) = I_m$

remark: (a) $\text{cov}(a) = E(aa^\top)$; (b) if $a \sim N(0, 1)^m$ then a isotropic

2. If rnd vect a isotropic, then $\forall x \in \mathbb{R}^m$ $E(\langle a, x \rangle^2) = \|x\|_2^2$
For two sq. symm. matrices B, C we have $B = C$ iff $\forall x (x^\top Bx = x^\top Cx)$;
hence $E(\langle a, x \rangle^2) = x^\top E(aa^\top)x = x^\top I_m x = \|x\|_2^2$

3. If rnd vect $a \in \mathbb{R}^m$ isotropic, then $E(\|a\|_2^2) = m$

$E(\|a\|_2^2) = E(a^\top a) = E(\text{tr}(a^\top a)) = E(\text{tr}(aa^\top)) = \text{tr}(E(aa^\top)) = \text{tr}(I_m) = m$

4. If rnd vect $a, c \in \mathbb{R}^m$ indep. isotropic, then $E(\langle a, c \rangle^2) = m$

By conditional expectation $E(\langle a, c \rangle^2) = E_c(E_a(\langle a, c \rangle^2 | c))$; by Item 2 inner expectation is $\|c\|_2^2$, by Item 3 outer is m

5. If $a \sim N(0, 1)^m$, $\|a\|_2 = O(\sqrt{m})$ w.h.p

by Thm. 3.1.1 in [Vershynin, 2018]

6. **Independent rnd vectors are almost orthogonal**

Results above $\Rightarrow \|a\|_2, \|c\|_2, \langle a, c \rangle = O(\sqrt{m})$, normalize a, c to \bar{a}, \bar{c} to get
 $\langle \bar{a}, \bar{c} \rangle = O(1/\sqrt{m}) \Rightarrow$ for m large $\langle \bar{a}, \bar{c} \rangle \approx 0$

Construction of A s.t. $\text{RIP}_s^\delta(A)$

- ▶ **Thm.** For $A \sim \mathbf{N}(0, 1)^{m \times n}$ and $\delta \in (0, 1) \exists C_1, C_2 > 0$ depending on δ s.t.

$$\forall s < m \left(m \geq \frac{s \ln(n/s)}{C_1} \rightarrow \text{Prob}(\text{RIP}_s^\delta(A)) \geq 1 - e^{-C_2 m} \right)$$

Pf. see Thm. 5.17 in [Damelin & Miller, 2012]

Remark: extra \sqrt{m} factor in A comes from $\|\cdot\|_2 \leq \|\cdot\|_1 \leq \sqrt{m} \|\cdot\|_2$

▶ In practice:

- ▶ $\text{Prob}(\text{RIP}_s^\delta(A)) = 0$ for m too small w.r.t. s fixed
- ▶ as m increases $\text{Prob}(\text{RIP}_s^\delta(A)) > 0$
- ▶ as m increases even more $\text{Prob}(\text{RIP}_s^\delta(A)) \rightarrow 1$ w.h.p
- ▶ achieve logarithmic compression for large n and fixed s
- ▶ $A \sim \mathbf{N}(0, 1)^{mn} \wedge m \geq 10s \ln \frac{n}{s} \Rightarrow \text{RIP}_s^{1/3}(A)$ w.h.p
Lem. 5.5.2 [Moitra 2018]
- ▶ works better than worst case bounds ensured by theory

Subsection 4

Application to noisy channel encoding

Noisy channel encoding procedure

Algorithm:

1. message: *character string* μ
2. $w = \text{string2bitlist}(\mu) \in \{0, 1\}^d$
3. send $z = Qw$, receive $\bar{z} = z + \hat{x}$, let $b = A\bar{z}$
 $\Delta = s/n = \text{density of } \hat{x}$, Q is $n \times d$ full rank with $n > d$
4. $x^* = \text{optimum of } P^1(A, b)$
5. $z^* = \bar{z} - x^*$
6. $w^* = \text{cap}(\text{round}((Q^\top Q)^{-1}Q^\top z^*), [0, 1])$
 $\text{cap}(t, [\alpha, \beta]) = (\alpha \text{ if } t < \alpha) \text{ xor } (\beta \text{ if } t > \beta) \text{ xor } (t \text{ othw})$
7. $\mu^* = \text{bitlist2string}(w^*)$
8. evaluate $\mu_{\text{err}} = \|\mu - \mu^*\|$

Parameter choice [Matousek]:

- ▶ noise $\Delta = 0.08$
- ▶ redundancy $n = Rd$, where $R = 4$

Finding orthogonal A, Q

- ▶ [Matousek, Gärtner 2007]:
 - ▶ sample A componentwise from $N(0, 1)$
 - ▶ then “find Q s.t. $QA = 0$ ”
 - ▶ *Gaussian elim. on underdet. system $AQ = 0$*
- ▶ Faster:
 - ▶ sample $n \times n$ matrix M from uniform distr
full rank with probability 1
 - ▶ find eigenvector matrix of $M^T M$ (orthonormal basis)
random rotation of standard basis (used in original JLL proof)
 - ▶ Concatenate d eigenvectors to make Q
Concatenate $m = n - d$ eigenvectors to make A
 $AQ = 0$ by construction!

Subsection 5

Improvements

LP size reduction

- ▶ Motivation

- ▶ Reduce CPU time spent on LP
- ▶ $R = 4$ redundancy for $\Delta = 0.08$ noise seems excessive

- ▶ Size of basis pursuit LP

- ▶ $Ax = b$ is an $m \times n$ system where $m = n - d$
- ▶ If $n = Rd \gg d$, m “relatively close” to n
- ▶ *Recall random projections for LP: use them!*

Computational results

d	n	Δ	ϵ	α	$\mu_{\text{err}}^{\text{org}}$	$\mu_{\text{err}}^{\text{prj}}$	CPU ^{org}	CPU ^{prj}
80	320	0.08	0.20	0.02	0	0	1.05	0.56
128	512	0.08	0.20	0.02	0	0	2.72	1.10
216	864	0.08	0.20	0.02	0	0	8.83	2.12
248	992	0.08	0.20	0.02	0	0	12.53	2.53
320	1280	0.08	0.20	0.02	0	0	23.70	3.35
408	1632	0.08	0.20	0.02	0	0	43.80	4.75

- ▶ $d = |\mu|$, $n = 4d$, $\Delta = 0.08$, $\epsilon = 0.2$
- ▶ $\alpha =$ Achlioptas density
 $P(T_{ij} = -1) = P(T_{ij} = 1) = \frac{\alpha}{2}$
 $P(T_{ij} = 0) = 1 - \alpha$
- ▶ $\mu_{\text{err}} =$ number of different characters
- ▶ CPU: seconds of elapsed time
- ▶ 1 sampling of A, Q, T

Sentence: *Conticuere omnes intentique ora tenebant, inde toro [...]*

Reducing redundancy in n

- ▶ *How about taking $n = (1 + \Delta)d$?*
- ▶ $m = n - d \approx \Delta d$ is very small
- ▶ Makes $Ax = b$ very short and fat
- ▶ Prevents compressed sensing from working correctly
not enough constraints
- ▶ **Would need both m and d to be $\approx n$ and $AQ = 0$:
impossible**
 \mathbb{R}^n too small to host $m + d \approx 2n$ orthogonal vectors
- ▶ Relax to $AQ \approx 0$?

Almost orthogonality by the JLL

Aim at A^\top, Q with $m + d \approx 2n$ and $AQ \approx 0$

- **JLL Corollary:** $\exists O(e^k)$ approx orthog vectors in \mathbb{R}^k

Pf. Let T be a $k \times p$ RP, use concentration of measure on $\|z\|_2^2$

$\text{Prob}((1 - \varepsilon)\|z\|_2^2 \leq \|Tz\|_2^2 \leq (1 + \varepsilon)\|z\|_2^2) \geq 1 - 2e^{-C(\varepsilon^2 - \varepsilon^3)k}$
given $x, y \in \mathbb{R}^p$ apply to $x + y$, $x - y$ and union bound:

$$\begin{aligned} |\langle Tx, Ty \rangle - \langle x, y \rangle| &= \frac{1}{4} \left| \|T(x+y)\|^2 - \|T(x-y)\|^2 - \|x+y\|^2 + \|x-y\|^2 \right| \\ &\leq \frac{1}{4} \left| \|T(x+y)\|^2 - \|x+y\|^2 \right| + \frac{1}{4} \left| \|T(x-y)\|^2 - \|x-y\|^2 \right| \\ &\leq \frac{\varepsilon}{4} (\|x+y\|^2 + \|x-y\|^2) = \frac{\varepsilon}{2} (\|x\|^2 + \|y\|^2) \end{aligned}$$

with prob $\geq 1 - 4e^{-C(\varepsilon^2 - \varepsilon^3)k}$; apply to std basis matrix I_p , get

$$-\varepsilon \leq \langle T\mathbf{e}_i, T\mathbf{e}_j \rangle - \langle \mathbf{e}_i, \mathbf{e}_j \rangle \leq \varepsilon$$

$\Rightarrow \exists p$ almost orthogonal vectors in \mathbb{R}^k , and $k = O(\frac{1}{\varepsilon^2} \ln p) \Rightarrow p = O(e^k)$

- **Algorithm:** $k = n, p = \lceil e^n \rceil$, get $2k$ columns from $T I_p$

Also see [<https://terrytao.wordpress.com/2013/07/18/a-cheap-version-of-the-kabatjanskii-levenstein-bound-for-almost-orthogonal-vectors/>]

Almost orthogonality by the JLL

- ▶ Aim at $m \times n$ A and $n \times m$ Q s.t. $AQ \approx 0$
with $n = (1 + \Delta')m$ and Δ' “small” (say $\Delta' < 1$)
- ▶ Need $2m$ approx orthog vectors in \mathbb{R}^n with $n < 2m$
- ▶ **Computationally: get large errors on $\|AQ\|_2$**
JLL theory requires exceedingly large sizes

- ▶ In fact, we only need $AQ = 0!$
can accept non-orthogonality in rows of A & cols of Q

Almost orthogonality by LP

- ▶ Sample Q and compute A using an LP
- ▶ $\max \sum_{\substack{i \leq m \\ j \leq n}} \text{Uniform}(-1, 1) A_{ij}$
- ▶ subject to $AQ = 0$ and $A \in [-1, 1]$
- ▶ for $m = 328$ and $n = 590$ (i.e. $\Delta' = 0.8$):
 - ▶ **error**: $\sum A_i Q^j = O(10^{-10})$
 - ▶ **rank**: full up to error precision (*not really though*)
 - ▶ **CPU**: 688s (*meh*)
- ▶ for $m = 328$ and $n = 492$ (i.e. $\Delta' = 0.5$): *the same*
- ▶ for $m = 328$ and $n = 426$ (i.e. $\Delta' = 0.3$): *CPU 470s*
- ▶ **Reduce CPU time by solving m LPs deciding A_i for all $i \leq m$**

Computational results

m	n	Δ'	$\mu_{\text{err}}^{\text{org}}$	$\mu_{\text{err}}^{\text{prj}}$	CPU ^{org}	CPU ^{prj}
328	426	0.3	182	15	2.45	1.87
328	426	0.3	154	0	2.20	1.49
328	459	0.4	0	1	4.47	2.45
328	459	0.4	5	17	2.86	1.46
328	492	0.5	60	0	4.53	1.18
328	492	0.5	34	0	5.38	1.18
328	590	0.8	14	0	8.30	1.41
328	590	0.8	107	4	6.76	1.43

- ▶ CPU for computing A, Q not counted:
precomputation is possible
- ▶ *Approximate beats precise!*

In summary

- ▶ If μ is short, set $\Delta' = \Delta$ and use compressed sensing (CS)
- ▶ If μ is longer, try increasing Δ' and use CS
- ▶ If μ is very long, use *JLL-projected CS*
- ▶ Can use approximately orthogonal A, Q too

*Conticuere omnes, intentique ora tenebant.
Inde toro pater Aeneas sic orsus ab alto:
Infandum, regina, iubes renovare dolorem.
Troianas ut opes et lamentabile regnum eruerint Danai
Quaequae ipse miserrima vidi et quorum pars magna fui.*
[Virgil, *Aeneid*, Cantus II]

$m = 1896, n = 2465$
 $\Delta' = 0.3$: min s.t. CS is accurate

method	error	CPU
CS	0	29.67s
JLL-CS	2	17.13s

These results are consistent over 3 samplings

Project idea 9: Implement and test RPs applied to CS, as described in the last slides. Aim at setting the redundancy n equal to the noise $(1 + \Delta)d$, and use CPLEX to compute A such that $AQ \approx 0$. Test your code on at least 10 different texts of various lengths, up to around 500 characters. How does decoding quality depend on $\|AQ\|_2$?

Outline

Introduction

- MP language
- Solvers
- MP systematics
- Some applications

Decidability

- Formal systems
- Gödel
- Turing
- Tarski
- Completeness and incompleteness
- MP solvability

Efficiency and Hardness

- Some combinatorial problems in NP
- NP-hardness
- Complexity of solving MP formulations

Summary

Random projections in LP

- Random projection theory
- Projecting LP feasibility
- Projecting LP optimality
- Solution retrieval
- Application to quantile regression

Sparsity and ℓ_1 minimization

- Motivation
- Basis pursuit
- Theoretical results
- Application to noisy channel encoding
- Improvements

Kissing Number Problem

- Lower bounds
- Upper bounds from SDP?
- Gregory's upper bound
- Delsarte's upper bound
- Pfender's upper bound

Clustering in Natural Language

- Clustering on graphs
- Clustering in Euclidean spaces
- Distance instability
- MP formulations
- Random projections again

Definition

- ▶ *Optimization version.* Given $K \in \mathbb{N}$, determine the maximum number $\text{kn}(K)$ of unit spheres that can be placed adjacent to a central unit sphere so their interiors do not overlap
- ▶ *Decision version.* Given $n, K \in \mathbb{N}$, is $\text{kn}(K) \leq n$?
in other words, determine whether n unit spheres can be placed adjacent to a central unit sphere so that their interiors do not overlap

Funny story: *Newton and Gregory went down the pub...*

Some examples

$$n = 6, K = 2$$

$$n = 12, K = 3$$

Radius formulation

Given $n, K \in \mathbb{N}$, determine whether there exist n vectors $x_1, \dots, x_n \in \mathbb{R}^K$ such that:

$$\begin{aligned} \forall i \leq n \quad \|x_i\|_2^2 &= 4 \\ \forall i < j \leq n \quad \|x_i - x_j\|_2^2 &\geq 4 \end{aligned}$$

Contact point formulation

Given $n, K \in \mathbb{N}$, determine whether there exist n vectors $x_1, \dots, x_n \in \mathbb{R}^K$ such that:

$$\begin{aligned} \forall i \leq n \quad \|x_i\|_2^2 &= 1 \\ \forall i < j \leq n \quad \|x_i - x_j\|_2^2 &\geq 1 \end{aligned}$$

Spherical codes

- ▶ $S^{K-1} \subset \mathbb{R}^K$ unit sphere centered at origin
- ▶ *K-dimensional spherical z-code*:
 - ▶ (finite) subset $\mathcal{C} \subset S^{K-1}$
 - ▶ $\forall x \neq y \in \mathcal{C} \quad x \cdot y \leq z$
- ▶ non-overlapping interiors:

$$\begin{aligned} \forall i < j \quad \|x_i - x_j\|_2^2 &\geq 1 \\ \Leftrightarrow \|x_i\|_2^2 + \|x_j\|_2^2 - 2x_i \cdot x_j &\geq 1 \\ \Leftrightarrow 1 + 1 - 2x_i \cdot x_j &\geq 1 \\ \Leftrightarrow 2x_i \cdot x_j &\leq 1 \\ \Leftrightarrow x_i \cdot x_j &\leq \frac{1}{2} = \cos\left(\frac{\pi}{3}\right) = z \end{aligned}$$

- ▶ we aim at maximizing $\text{kn}_z(K) \triangleq |\mathcal{C}|$
let $\text{kn}(K) = \text{kn}_{\frac{1}{2}}(K)$

Subsection 1

Lower bounds

Lower bounds

- ▶ Construct spherical $\frac{1}{2}$ -code \mathcal{C} with $|\mathcal{C}|$ large
- ▶ Nonconvex NLP formulations
- ▶ SDP relaxations
- ▶ Combination of the two techniques

MINLP formulation

Maculan, Michelon, Smith 1995

Parameters:

- ▶ K : space dimension
- ▶ n : upper bound to $\text{kn}(K)$

Variables:

- ▶ $x_i \in \mathbb{R}^K$: contact pt. of i -th surrounding sphere
- ▶ $\alpha_i = 1$ iff sphere i in configuration

$$\left. \begin{array}{ll} \max & \sum_{i=1}^n \alpha_i \\ \forall i \leq n & \|x_i\|^2 = \alpha_i \\ \forall i < j \leq n & \|x_i - x_j\|^2 \geq \alpha_i \alpha_j \\ \forall i \leq n & x_i \in [-1, 1]^K \\ \forall i \leq n & \alpha_i \in \{0, 1\} \end{array} \right\}$$

Reformulating the binary products

- ▶ **Additional variables:** $\beta_{ij} = 1$ iff vectors i, j in configuration
- ▶ Linearize $\alpha_i \alpha_j$ by β_{ij}
- ▶ **Add constraints:**

$$\forall i < j \leq n \quad \beta_{ij} \leq \alpha_i$$

$$\forall i < j \leq n \quad \beta_{ij} \leq \alpha_j$$

$$\forall i < j \leq n \quad \beta_{ij} \geq \alpha_i + \alpha_j - 1$$

Computational experiments

AMPL and Baron

▶ **Certifying YES**

- ▶ $n = 6, K = 2$: OK, 0.60s
- ▶ $n = 12, K = 3$: OK, 0.07s
- ▶ $n = 24, K = 4$: FAIL, CPU time limit (100s)

▶ **Certifying NO**

What about polar coordinates?

- ▶ $\forall i \leq n \quad \mathbf{x}_i = (x_{i1}, \dots, x_{iK}) \mapsto (\vartheta_{i1}, \dots, \vartheta_{i,K-1})$
- ▶ Formulation

$$(\dagger) \quad \forall k \leq K \quad \rho \sin \vartheta_{i,k-1} \prod_{h=k}^{K-1} \cos \vartheta_{ih} = x_{ik}$$

$$(\ddagger) \quad \forall i < j \leq n \quad \|\mathbf{x}_i - \mathbf{x}_j\|_2^2 \geq \rho^2$$

$$\forall i \leq n, k \leq K \quad (\sin(\vartheta_{ik}))^2 + (\cos(\vartheta_{ik}))^2 = 1$$

$$(optional) \quad \rho = 1$$

- ▶ Only need to decide $s_{ik} = \sin \vartheta_{ik}$ and $c_{ik} = \cos \vartheta_{ik}$
- ▶ Replace x in (\ddagger) using (\dagger) : get polyprog in s, c
- ▶ *Numerically more challenging to solve (polydeg $2K$)*
- ▶ OPEN QUESTION: useful for bounds?

Subsection 2

Upper bounds from SDP?

SDP relaxation of Euclidean distances

- ▶ Linearization of scalar products

$$\forall i, j \leq n \quad x_i \cdot x_j \longrightarrow X_{ij}$$

where X is an $n \times n$ symmetric matrix

- ▶ $\|x_i\|_2^2 = x_i \cdot x_i = X_{ii}$
- ▶ $\|x_i - x_j\|_2^2 = \|x_i\|_2^2 + \|x_j\|_2^2 - 2x_i \cdot x_j = X_{ii} + X_{jj} - 2X_{ij}$
- ▶ $X = xx^\top \Rightarrow X - xx^\top = 0$ makes linearization exact
- ▶ Relaxation:

$$X - xx^\top \succeq 0 \Rightarrow \text{Schur}(X, x) = \begin{pmatrix} I_K & x^\top \\ x & X \end{pmatrix} \succeq 0$$

SDP relaxation of binary constraints

- ▶ $\forall i \leq n \quad \alpha_i \in \{0, 1\} \Leftrightarrow \alpha_i^2 = \alpha_i$
- ▶ Let A be an $n \times n$ symmetric matrix
- ▶ Linearize $\alpha_i \alpha_j$ by A_{ij} (hence α_i^2 by A_{ii})
- ▶ $A = \alpha \alpha^\top$ makes linearization exact
- ▶ **Relaxation:** $\text{Schur}(A, \alpha) \succeq 0$

SDP relaxation of [MMS95]

$$\begin{array}{rcl}
 \max & \sum_{i=1}^n \alpha_i & \\
 \forall i \leq n & X_{ii} = \alpha_i & \\
 \forall i < j \leq n & X_{ii} + X_{jj} - 2X_{ij} \geq A_{ij} & \\
 \forall i \leq n & A_{ii} = \alpha_i & \\
 \forall i < j \leq n & A_{ij} \leq \alpha_j & \\
 \forall i < j \leq n & A_{ij} \leq \alpha_i & \\
 \forall i < j \leq n & A_{ij} \geq \alpha_i + \alpha_j - 1 & \\
 & \text{Schur}(X, x) \succeq 0 & \\
 & \text{Schur}(A, \alpha) \succeq 0 & \\
 \forall i \leq n & x_i \in [-1, 1]^K & \\
 & \alpha \in [0, 1]^n & \\
 & X \in [-1, 1]^{n^2} & \\
 & A \in [0, 1]^{n^2} &
 \end{array}
 \left. \vphantom{\begin{array}{rcl}} \right\}$$

Computational experiments

- ▶ Python, PICOS and Mosek
or Octave and SDPT3

- ▶ bound always equal to n

- ▶ prominent failure :-)

- ▶ **Why?**

- ▶ *can combine inequalities to remove A from SDP*

$$\begin{aligned}\forall i < j \quad X_{ii} + X_{jj} - 2X_{ij} &\geq A_{ij} \geq \alpha_i + \alpha_j - 1 \\ \Rightarrow X_{ii} + X_{jj} - 2X_{ij} &\geq \alpha_i + \alpha_j - 1\end{aligned}$$

(then eliminate all constraints in A)

- ▶ *integrality of α completely lost*

SDP relaxation of [KBLM07]

$$\left. \begin{array}{ll} \max & \alpha \\ \forall i \leq n & X_{ii} = 1 \\ \forall i < j \leq n & X_{ii} + X_{jj} - 2X_{ij} \geq \alpha \\ & X \in [-1, 1]^{n^2} \\ & X \succeq 0 \\ & \alpha \geq 0 \end{array} \right\}$$

Computational experiments

With $K = 2$

n	α^*
2	4.00
3	3.00
4	2.66
5	2.50
6	2.40
7	2.33
8	2.28
9	2.25
10	2.22
11	2.20
12	2.18
13	2.16
14	2.15
15	2.14

Computational experiments

With $K = 3$

Always $\rightarrow 2$?

An SDP-based heuristic?

1. $X^* \in \mathbb{R}^{n^2}$: SDP relaxation solution of [KBLM07]
2. Perform PCA, get $\bar{x} \in \mathbb{R}^{nK}$
3. Local NLP solver on [KBLM07] with starting point \bar{x}

However...

The Uselessness Theorem

Thm.

1. The SDP relaxation of [KBLM07] is useless
2. In fact, it is *extremely* useless

1. Part 1: Uselessness

▶ *Independent of K :*

no useful bounds in function of K

2. Part 2: Extreme uselessness

(a) *For all n , the bound is $\frac{2n}{n-1}$*

(b) *\exists opt. X^* with eigenvalues $0, \frac{n}{n-1}, \dots, \frac{n}{n-1}$*

By 2(b), applying MDS/PCA makes no sense

Proof of extreme uselessness

Strategy:

- ▶ Pull a simple matrix solution out of a hat
- ▶ Write primal and dual SDP of [KBLM07]
- ▶ Show it is feasible in both
- ▶ Hence it is optimal
- ▶ Analyse solution:
 - ▶ all $n - 1$ positive eigenvalues are equal
 - ▶ its objective function value is $2n/(n - 1)$

Primal SDP

$\forall 1 \leq i \leq j \leq n$ let $B_{ij} = (1_{ij})$ and 0 elsewhere

<i>quantifier</i>	<i>natural form</i>	<i>standard form</i>	<i>dual var</i>
$\forall i \leq n$	$\max \alpha$	$\max \alpha$	
$\forall i < j \leq n$	$X_{ii} = 1$	$E_{ii} \bullet X = 1$	u_i
$\forall i < j \leq n$	$X_{ii} + X_{jj} - 2X_{ij} \geq \alpha$	$A_{ij} \bullet X + \alpha \leq 0$	w_{ij}
$\forall i < j \leq n$	$X_{ij} \leq 1$	$A_{ij} = -E_{ii} - E_{jj} + E_{ij} + E_{ji}$	
$\forall i < j \leq n$	$X_{ij} \geq -1$	$(E_{ij} + E_{ji}) \bullet X \leq 2$	y_{ij}
	$X \succeq 0$	$(-E_{ij} - E_{ji}) \bullet X \leq 2$	z_{ij}
	$\alpha \geq 0$	$X \succeq 0$	
		$\alpha \geq 0$	

Dual SDP

$$\begin{aligned} & \min \sum_i u_i + 2 \sum_{i < j} (y_{ij} + z_{ij}) \\ & \sum_i u_i E_{ii} + \sum_{i < j} ((y_{ij} - z_{ij})(E_{ij} - E_{ji}) + w_{ij} A_{ij}) \succeq 0 \\ & \sum_{i < j} w_{ij} \geq 1 \\ & w, y, z \geq 0 \end{aligned}$$

Simplify $|v| = y + z$, $v = y - z$:

$$\begin{aligned} & \min \sum_i u_i + 2 \sum_{i < j} |v_{ij}| \\ & \sum_i u_i E_{ii} + \sum_{i < j} (v_{ij}(E_{ij} - E_{ji}) + w_{ij} A_{ij}) \succeq 0 \\ & \sum_{i < j} w_{ij} \geq 1 \\ & w, v \geq 0 \end{aligned}$$

Pulling a solution out of a hat

$$\begin{aligned}\alpha^* &= \frac{2n}{n-1} \\ X^* &= \frac{n}{n-1}I_n - \frac{1}{n-1}\mathbf{1}_n \\ u^* &= \frac{2}{n-1} \\ w^* &= \frac{1}{n(n-1)} \\ v^* &= 0\end{aligned}$$

where $\mathbf{1}_n =$ all-one $n \times n$ matrix

Solution verification

- ▶ linear constraints: *by inspection*
- ▶ $X \succeq 0$: *eigenvalues of X^* are $0, \frac{n}{n-1}, \dots, \frac{n}{n-1}$*
- ▶ $\sum_i u_i E_{ii} + \sum_{i < j} (v_{ij}(E_{ij} - E_{ji}) + w_{ij}A_{ij}) \succeq 0$:

$$\begin{aligned} & \sum_i u_i^* E_{ii} + \sum_{i < j} w_{ij}^* A_{ij} \\ = & \frac{2}{n-1} \sum_i E_{ii} + \frac{1}{n(n-1)} \sum_{i < j} A_{ij} \\ = & \frac{2}{n-1} I_n + \frac{1}{n(n-1)} (-(n-1)I_n + (\mathbf{1}_n - I_n)) \\ = & \frac{1}{n(n-1)} \mathbf{1}_n \succeq 0 \end{aligned}$$

Corollary

$$\lim_{n \rightarrow \infty} v(n, [\text{KBLM07}]) = \lim_{n \rightarrow \infty} \frac{2n}{n-1} = 2$$

as observed in computational experiments

Subsection 3

Gregory's upper bound

Surface upper bound

Gregory 1694, Szpiro 2003

Consider a $kn(3)$ configuration inscribed into a super-sphere of radius 3. Imagine a lamp at the centre of the central sphere that casts shadows of the surrounding balls onto the inside surface of the super-sphere. Each shadow has a surface area of 7.6; the total surface of the super-ball is 113.1. So $\frac{113.1}{7.6} = 14.9$ is an upper bound to $kn(3)$.

At end of XVII century, yielded Newton/Gregory dispute

Subsection 4

Delsarte's upper bound

Pair distribution on sphere surface

- ▶ Spherical z -code \mathcal{C} has $x_i \cdot x_j \leq z$ ($i < j \leq n = |\mathcal{C}|$)

$$\forall t \in [-1, 1] \quad \sigma_t = \frac{1}{n} |\{(i, j) \mid i, j \leq n \wedge x_i \cdot x_j = t\}|$$

- ▶ z -code: let $\sigma_t = 0$ for $t \in (z, 1)$ ($z = 1/2$ for KNP)
- ▶ $|\mathcal{C}| = n < \infty$: only finitely many $\sigma_t \neq 0$

$$\int_{[-1,1]} \sigma_t dt = \sum_{\substack{t \in [-1,1] \\ \sigma_t \neq 0}} \sigma_t = \frac{1}{n} |\text{all pairs}| = \frac{n^2}{n} = n$$

$$\sigma_1 = \frac{1}{n} = 1$$

$$\forall t \in (z, 1) \quad \sigma_t = 0$$

$$\forall t \in [-1, 1] \quad \sigma_t \geq 0$$

$$|\{\sigma_t > 0 \mid t \in [-1, 1]\}| < \infty$$

Growing Delsarte's LP

- ▶ Decision variables: σ_t , for $t \in [-1, 1]$
- ▶ Objective function:

$$\begin{aligned}\max |\mathcal{C}| = \max n &= \max_{\sigma} \sum_{\substack{t \in [-1, 1] \\ \sigma_t \neq 0}} \sigma_t \\ &= \sigma_1 + \max_{\sigma} \sum_{\substack{t \in [-1, z] \\ \sigma_t \neq 0}} \sigma_t = 1 + \max_{\sigma} \sum_{\substack{t \in [-1, z] \\ \sigma_t \neq 0}} \sigma_t\end{aligned}$$

Note n not a parameter in this formulation

- ▶ Constraints:

$$\forall t \in [-1, z] \quad \sigma_t \geq 0$$

- ▶ **LP unbounded!** — need more constraints

The general approach

- ▶ We need σ to encode the fact that

$$\forall t \in [-1, 1] \quad \sigma_t = \frac{1}{n} |\{(i, j) \mid i, j \leq n \wedge x_i \cdot x_j = t\}|$$

- ▶ We use the algebraic theory in [Delsarte et al., “Spherical codes and designs”, *Geometriae Dedicata* 6:363-388, 1977]
- ▶ It involves the expression of a non-negative polynomial by means of a linear combination of Gegenbauer polynomials weighted by the σ_t

I will skip over the details

- ▶ You can also see the proof in [Odlyzko, Sloane, “New bounds on the number of unit spheres that can touch a unit sphere in n dimensions”, *J. of Comb. Theory A*, 26:210-214, 1979]

Gegenbauer cuts

- ▶ Look for function family $\mathcal{F} : [-1, 1] \rightarrow \mathbb{R}$ s.t.

$$\forall \phi \in \mathcal{F} \quad \sum_{\substack{t \in [-1, 1] \\ \sigma_t \neq 0}} \phi(t) \sigma_t \geq 0$$

- ▶ Most popular \mathcal{F} : *Gegenbauer polynomials* G_h^K
- ▶ Special case $G_h^K = P_h^{\gamma, \gamma}$ of *Jacobi polynomials* (where $\gamma = (K - 2)/2$)

$$P_h^{\alpha, \beta}(t) = \frac{1}{2^h} \sum_{i=0}^h \binom{h + \alpha}{i} \binom{h + \beta}{h - i} (t + 1)^i (t - 1)^{h - i}$$

- ▶ Matlab knows them: $G_h^K(t) = \text{gegenbauerC}(h, (K - 2)/2, t)$
- ▶ Octave knows them: $G_h^K(t) = \text{gsl_sf_gegenpoly_n}(h, \frac{K-2}{2}, t)$
need command pkg load gsl before function call
- ▶ **They encode dependence on K**

Delsarte's LP

- **Primal:** (given some Gegenbauer polynomial index set H)

$$\left. \begin{array}{l} 1 + \max \sum_{t \in [-1, \frac{1}{2}]} \sigma_t \\ \forall h \in H \sum_{\substack{t \in [-1, \frac{1}{2}] \\ \sigma_t \neq 0}} G_h^K(t) \sigma_t \geq -G_h^K(1) \\ \forall t \in [-1, z] \sigma_t \geq 0. \end{array} \right\} \text{[DelP]}$$

MP syntax error: decision variables σ in sum quantifier!

- **Dual:**

$$\left. \begin{array}{l} 1 + \min \sum_{h \in H} (-G_h^K(1)) d_h \\ \forall t \in [-1, z] \sum_{h \in H} G_h^K(t) d_h \geq 1 \\ \forall h \in H d_h \leq 0. \end{array} \right\} \text{[DelD]}$$

Delsarte's theorem

- ▶ [Delsarte *et al.*, 1977; Odlyzko & Sloane, 1979]

Theorem

Let $d \in \mathbb{R}_+^\ell$ with $d_0 > 0$, and $F : [-1, 1] \rightarrow \mathbb{R}$ s.t.:

(i) $\forall t \in [-1, 1] \quad F(t) = \sum_{h \leq \ell} d_h G_h^K(t)$

(ii) $\forall t \in [-1, z] \quad F(t) \leq 0$

Then $\text{kn}_z(K) \leq \frac{F(1)}{d_0}$

- ▶ *Proof based on properties of Gegenbauer polynomials*
- ▶ **Best upper bound:** $\min F(1)/d_0 \Rightarrow \min_{d_0=1} F(1) \Rightarrow [\text{DelD}]$
- ▶ [DelD] “models” Delsarte's theorem (take $\ell = |H|$)

Delsarte's normalized LP ($G_h^K(1) = 1$)

► Primal:

$$\left. \begin{array}{l}
 1 + \max \quad \sum_{\substack{t \in [-1, \frac{1}{2}] \\ \sigma_t \neq 0}} \sigma_t \\
 \forall h \in H \quad \sum_{\substack{t \in [-1, \frac{1}{2}] \\ \sigma_t \neq 0}} G_h^K(t) \sigma_t \geq -1 \\
 \forall t \in [-1, \frac{1}{2}] \quad \sigma_t \geq 0
 \end{array} \right\} \text{[DelP]}$$

► Dual:

$$\left. \begin{array}{l}
 1 + \min \quad \sum_{h \in H} (-1) d_h \\
 \forall t \in [-1, \frac{1}{2}] \quad \sum_{h \in H} G_h^K(t) d_h \geq 1 \\
 \forall h \in H \quad d_h \leq 0
 \end{array} \right\} \text{[DelD]}$$

► $d_0 = 1 \Rightarrow$ remove 0 from H

Focus on normalized [DelD]

Rewrite $-d_h$ as d_h :

$$\left. \begin{array}{l} 1 + \min \\ \forall t \in [-1, \frac{1}{2}] \\ \forall h \in H \end{array} \right\} \left. \begin{array}{l} \sum_{h \in H} d_h \\ \sum_{h \in H} G_h^K(t) d_h \leq -1 \\ d_h \geq 0 \end{array} \right\} [\text{DelD}]$$

Issue: *semi-infinite LP (SILP)* (how do we solve it?)

Approximate SILP solution

- ▶ *Only keep finitely many constraints*
- ▶ Discretize $[-1, 1]$ with a finite $T \subset [-1, 1]$
- ▶ Obtain relaxation $[\text{DeID}]_T$:

$$\text{val}([\text{DeID}]_T) \leq \text{val}([\text{DeID}])$$

- ▶ **Risk:** $\text{val}([\text{DeID}]_T) < \min F(1)/d_0$
not a valid upper bound to $\text{kn}_z(K)$
- ▶ Happens if soln. of $[\text{DeID}]_T$ infeasible in $[\text{DeID}]$
i.e. infeasible w.r.t. some of the ∞ many removed constraints

SILP feasibility

- ▶ Given SILP $\bar{S} \equiv \min\{c^\top x \mid \forall t \in \bar{T} \langle a(t), x \rangle \leq b(t)\}$
- ▶ Relax to LP $S \equiv \min\{c^\top x \mid \forall t \in T \langle a(t), x \rangle \leq b(t)\}$
with $T \subsetneq \bar{T}$ and $|T| < \infty$
- ▶ Solve S , get solution x^*
- ▶ Let $\epsilon = \max_t \{\langle a(t), x^* \rangle - b(t) \mid t \in \bar{T}\}$

continuous NLP with a single var. t
- ▶ If $\epsilon \leq 0$ then x^* feasible in \bar{S}
 $\Rightarrow \text{val}(\bar{S}) \leq c^\top x^*$
- ▶ If $\epsilon > 0$ refine S and repeat
- ▶ Apply to $[\text{DelD}]_T$, get solution d^* feasible in $[\text{DelD}]$

[DelD] feasibility

1. Choose discretization T of $[-1, z]$

2. Solve

$$\left. \begin{array}{l} 1 + \min \sum_{h \in H} d_h \\ \forall t \in T \quad \sum_{h \in H} G_h^K(t) d_h \leq -1 \\ \forall h \in H \quad d_h \geq 0 \end{array} \right\} [\text{DelD}]_T$$

get solution d^*

3. Solve PP $\epsilon = \max_t \{1 + \sum_{h \in H} G_h^K(t) d_h^* \mid t \in [-1, z]\}$

4. If $\epsilon \leq 0$ then d^* feasible in [DelD]

$$\Rightarrow \text{kn}_z(K) \leq 1 + \sum_{h \in H} d_h^*$$

5. Else refine T and repeat from Step 2

Subsection 5

Pfender's upper bound

Pfender's upper bound theorem

Thm.

Let $\mathcal{C}_z = \{x_i \in \mathbb{S}^{K-1} \mid i \leq n \wedge \forall j \neq i (x_i \cdot x_j \leq z)\}$; $c_0 > 0$; $f : [-1, 1] \rightarrow \mathbb{R}$ s.t.:

(i) $\sum_{i,j \leq n} f(x_i \cdot x_j) \geq 0$ (ii) $f(t) + c_0 \leq 0$ for $t \in [-1, z]$ (iii) $f(1) + c_0 \leq 1$

Then $\text{kn}_z(K) = n \leq \frac{1}{c_0}$

([Pfender 2006])

Let $g(t) = f(t) + c_0$

$$\begin{aligned} n^2 c_0 &\leq n^2 c_0 + \sum_{i,j \leq n} f(x_i \cdot x_j) && \text{by (i)} \\ &= \sum_{i,j \leq n} (f(x_i \cdot x_j) + c_0) = \sum_{i,j \leq n} g(x_i \cdot x_j) \\ &\leq \sum_{i \leq n} g(x_i \cdot x_i) && \text{since } g(t) \leq 0 \text{ for } t \leq z \text{ and } x_i \in \mathcal{C}_z \text{ for } i \leq n \\ &= ng(1) && \text{since } \|x_i\|_2 = 1 \text{ for } i \leq n \\ &\leq n && \text{since } g(1) \leq 1. \end{aligned}$$

Pfender's LP

- ▶ Condition (i) of **Theorem** valid for conic combinations of **suitable functions** \mathcal{F} :

$$f(t) = \sum_{h \in H} c_h f_h(t) \quad \text{where } c_h \geq 0 \text{ for } h \in H,$$

e.g. $\mathcal{F} =$ Gegenbauer polynomials (again)

- ▶ Get SILP

$$\left. \begin{array}{ll} \max_{c \in \mathbb{R}^{|H|}} & c_0 \quad (\text{minimize } 1/c_0 \geq n) \\ \forall t \in [-1, z] & \sum_{h \in H} c_h G_h^K(t) + c_0 \leq 0 \quad (\text{ii}) \\ & \sum_{h \in H} c_h G_h^K(1) + c_0 \leq 1 \quad (\text{iii}) \\ \forall h \in H & c_h \geq 0 \quad (\text{conic comb.}) \end{array} \right\}$$

- ▶ *Discretize $[-1, z]$ by finite T , solve LP, check validity (again)*

Delsarte's and Pfender's theorem compared

- ▶ Delsarte & Pfender's theorem look similar:

Delsarte	Pfender
(i) $F(t)$ G. poly comb	(i) $f(t)$ G. poly comb
(ii) $\forall t \in [-1, z] F(t) \leq 0$	(ii) $\forall t \in [-1, z] f(t) + c_0 \leq 0$
$\Rightarrow \text{kn}_z(K) \leq \frac{F(1)}{d_0}$	(iii) $f(1) + c_0 \leq 1$ $\Rightarrow \text{kn}_z(K) \leq \frac{1}{c_0}$

- ▶ **Try setting** $F(t) = f(t) + c_0$: condition (ii) is the same
- ▶ By condition (iii) in Pfender's theorem

$$\text{kn}_z(K) \leq \frac{F(1)}{d_0} = \frac{f(1) + c_0}{c_0} \leq \frac{1}{c_0}$$

\Rightarrow Delsarte bound at least as tight as Pfender's

- ▶ Delsarte (i) $\Rightarrow \int_{[-1,1]} F(t)dt \geq 0 \Rightarrow \int_{[-1,1]} (f(t) + c_0)dt \geq 0$
Pfender (i) $\Rightarrow \int_{[-1,1]} f(t)dt \geq 0$ more stringent

*If \mathcal{F} are Gegenbauer polynomials, Delsarte requires weaker condition and yields tighter bound; but Pfender allows for more general \mathcal{F} , can get improved results see [Pfender, "Improved Delsarte bounds for spherical codes in small dimensions", *J. Comb. Theory A*, 114:1133-1147, 2007]*

The final, easy improvement

- ▶ However you compute your upper bound B :
- ▶ The number of surrounding balls is *integer*
- ▶ If $\text{kn}_z(K) \leq B$, then in fact $\text{kn}_z(K) \leq \lfloor B \rfloor$

Outline

Introduction

- MP language
- Solvers
- MP systematics
- Some applications

Decidability

- Formal systems
- Gödel
- Turing
- Tarski
- Completeness and incompleteness
- MP solvability

Efficiency and Hardness

- Some combinatorial problems in NP
- NP-hardness
- Complexity of solving MP formulations

A typical job offer

Under the responsibility of the Commercial Director, the Optimisation / Operations Senior Manager will have the responsibility to optimise and develop operational aspects for VINCI Airports current and future portfolio of airports. They will also be responsible for driving forward and managing key optimisation projects that assist the Commercial Director in delivering the objectives of the Technical Services Agreements activities of VINCI Airports. The Optimisation Manager will support the Commercial Director in the development and implementation of plans, strategies and reporting processes. As part of the exercise of its function, the Optimisation Manager will undertake the following: Identification and development of cross asset synergies with a specific focus on the operations and processing functions of the airport. Definition and implementation of the Optimisation Strategy in line with the objectives of the various technical services agreements, the strategy of the individual airports and the Group. This function will include: Participation in the definition of airport strategy. Definition of this airport strategy into the Optimisation Strategy. Regularly evaluate the impact of the Optimisation Strategy. Ensure accurate implementation of this strategy at all airports. Management of the various technical services agreements with our airports by developing specific technical competences from the Head Office level. Oversee the management and definition of all optimisation projects. Identification, overview and management of the project managers responsible for the delivery of the various optimization projects at each asset. Construction of good relationships with the key stakeholders, in order to contribute to the success of each optimization project. Development and implementation of the Group optimisation plan. Definition of economic and quality of service criteria, in order to define performance goals. Evaluation of the performance of the Group operations in terms of processing efficiency, service levels, passenger convenience and harmonization of the non-aeronautical activities. Monitoring the strategies, trends and best practices of the airport industry and other reference industries in terms of the applicability to the optimization plan. Study of the needs and preferences of the passengers, through a continuous process of marketing research at all of the airports within the VINCI Airports portfolio. Development of benchmarking studies in order to evaluate the trends, in international airports or in the local market. Development and participation in the expansion or refurbishment projects of the airports, to assure a correct configuration and positioning of the operational and commercial area that can allow the optimization of the revenues and operational efficiency. Support the Director Business Development through the analysis and opportunity assessment of areas of optimization for all target assets in all bids and the preparation and implementation of the strategic plan once the assets are acquired. Maintain up to date knowledge of market trends and key initiatives related to the operational and commercial aspects of international airports [...]

... and blah blah blah: IS THIS APPROPRIATE FOR MY CV?

Rationalizing the application process

- ▶ You collect many offers
- ▶ Don't have time to tailor application to each offer
- ▶ Partition offers into groups: clustering
- ▶ *Need a similarity relation*
given two offers, do they describe “similar jobs”?
- ▶ Try Natural Language Processing (NatLangProc):
 - ▶ *Automated summary*
 - ▶ *Relation Extraction*
 - ▶ *Named Entity Recognition* (NER)
 - ▶ *Keywords*

Automated summary

```
./summarize.py job01.txt
```

They will also be responsible for driving forward and managing key optimisation projects that assist the Commercial Director in delivering the objectives of the Technical Services Agreements activities of VINCI Airports. The Optimisation Manager will support the Commercial Director in the development and implementation of plans, strategies and reporting processes. Identification and development of cross asset synergies with a specific focus on the operations and processing functions of the airport. Construction of good relationships with the key stakeholders, in order to contribute to the success of each optimization project. Definition of economic and quality of service criteria, in order to define performance goals. Evaluation of the performance of the Group operations in terms of processing efficiency, service levels, passenger convenience and harmonization of the non-aeronautical activities. Development of benchmarking studies in order to evaluate the trends, in international airports or in the local market. Maintain up to date knowledge of market trends and key initiatives related to the operational and commercial aspects of international airports. You have a diverse range of experiences working at or with airports across various disciplines such as operations, ground handling, commercial, etc. Demonstrated high level conceptual thinking, creativity and analytical skills.

Does it help? hard to say

For a document D , let $\text{NER}(D)$ = named entity words

Subsection 1

Clustering on graphs

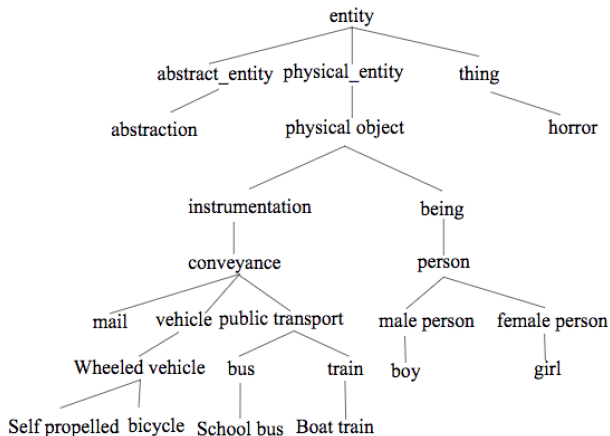

Constructing the graph

1. Recognize **named entities** from all documents
2. Use them to compute **similarities** among documents
3. Use **modularity clustering**

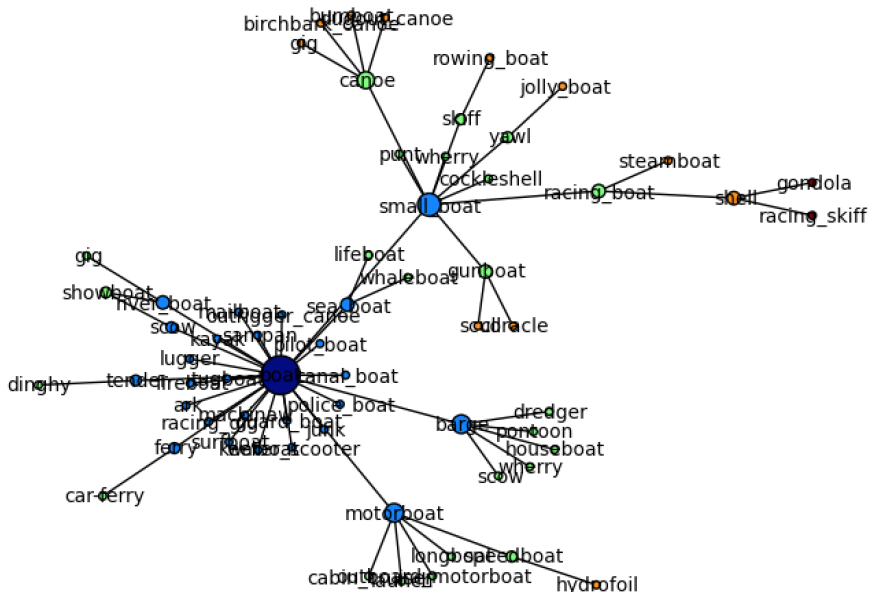

The named entities

1. *Operations Head Airports Office VINCI Technical Self French / Strategy Agreements English Services Optimisation*
2. *Europe and P&C Work Optimization Head He/she of Price Global PhDs Direct Asia Earnix AGD AXA Innovation Coordinate International English*
3. *Scientist Product Analyze Java Features & Statistics Science PHP Pig/Hive/Spark Optimization Crunch/analyze Team Press Performance Deezer Data Computer*
4. *Lean6Sigma Lean-type Office Banking Paris CDI France RPA Middle Accenture English Front Benelux*

Word similarity: WordNet

WordNet: hyponyms of “boat”

Wu-Palmer word similarity

Semantic WordNet similarity between words w_1, w_2 :

$$\text{wup}(w_1, w_2) = \frac{2 \text{depth}(\text{lca}(w_1, w_2))}{\text{len}(\text{shpath}(w_1, w_2)) + 2 \text{depth}(\text{lca}(w_1, w_2))}$$

▶ *lca*: *lowest common ancestor*

earliest common word in paths from both words to WordNet root

▶ *depth*: *length of path from root to word*

Example: $\text{wup}(\text{dog}, \text{boat})$?

$\text{lca}(\text{dog}, \text{boat}) = \text{whole}$; $\text{depth}(\text{whole}) = 4$

18 -> dog -> canine -> carnivore -> placental -> mammal -> vertebrate
-> chordate -> animal -> organism -> living_thing -> whole -> artifact
-> instrumentality -> conveyance -> vehicle -> craft -> vessel -> boat

13 -> dog -> domestic_animal -> animal -> organism -> living_thing
-> whole -> artifact -> instrumentality -> conveyance -> vehicle
-> craft -> vessel -> boat

$$\text{wup}(\text{dog}, \text{boat}) = 8/21 = 0.380952380952$$

Extensions of Wu-Palmer similarity

- ▶ to lists of words H, L :

$$\text{wup}(H, L) = \frac{1}{|H||L|} \sum_{v \in H} \sum_{w \in L} \text{wup}(v, w)$$

- ▶ to pairs of documents D_1, D_2 :

$$\text{wup}(D_1, D_2) = \text{wup}(\text{NER}(D_1), \text{NER}(D_2))$$

- ▶ wup and its extensions are always in $[0, 1]$

The Wu-Palmer similarity matrix

The similarity graph

$G = (V, E)$, weighted adjacency matrix A

Modularity clustering

“Modularity is the fraction of the edges that fall within a cluster minus the expected fraction if edges were distributed at random.”

- ▶ “at random” = random graphs over same degree sequence
- ▶ degree sequence = (k_1, \dots, k_n) where $k_i = |N(i)|$
- ▶ “expected” = over all possible “half-edge” recombinations
degree sequence invariant operation

- ▶ expected edges between u, v : $k_u k_v / (2m)$ where $m = |E|$
- ▶ $\text{mod}(u, v) = \frac{1}{2m} (A_{uv} - k_u k_v / (2m))$ param
- ▶ $\text{mod}(G) = \sum_{\{u,v\} \in E} \text{mod}(u, v) x_{uv}$
 $x_{uv} = 1$ if u, v in the same cluster and 0 otherwise var
- ▶ “Natural extension” to weighted graphs: $k_u = \sum_v A_{uv}$, $m = \sum_{uv} A_{uv}$

Use modularity to define clustering

- ▶ What is the “best clustering”?
- ▶ *Maximize discrepancy between actual and expected*
“as far away as possible from average”

$$\left. \begin{array}{l} \max \sum_{\{u,v\} \in E} \text{mod}(u,v)x_{uv} \\ \forall u \in V, v \in V \quad x_{uv} \in \{0, 1\} \end{array} \right\}$$

- ▶ **Issue:** optimum could be intransitive
- ▶ **Idea:** *treat clusters as cliques (even if zero weight)*
 \Rightarrow *clique partitioning constraints for transitivity*

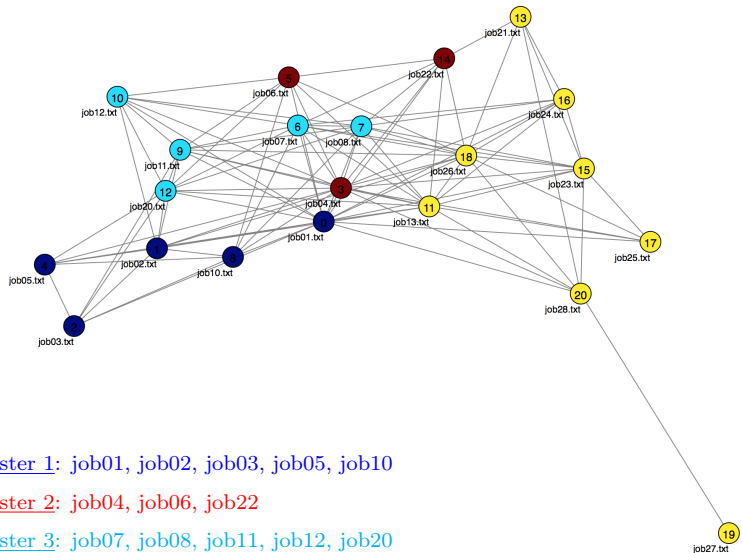

$$\forall i < j < k \quad x_{ij} + x_{jk} - x_{ik} \leq 1$$

$$\forall i < j < k \quad x_{ij} - x_{jk} + x_{ik} \leq 1$$

$$\forall i < j < k \quad -x_{ij} + x_{jk} + x_{ik} \leq 1$$

if $i, j \in C$ and $j, k \in C$ then $i, k \in C$

The resulting clustering

cluster 1: job01, job02, job03, job05, job10

cluster 2: job04, job06, job22

cluster 3: job07, job08, job11, job12, job20

cluster 4: job13, job21, job23, job24, job25, job26, job27, job28

Is it good?

Vinci	Accenture	Elektrobit	Amazon 1-3
Axa	Expedia	Google	CSX
Deezer	fragment1	Ford	Westrock
Alstom		Marriott	Mitre
Aledade		Llamasoft	Clarity
			fragment2

- ▶ ? — *named entities rarely appear in WordNet*
- ▶ *Desirable property: chooses number of clusters*

Subsection 2

Clustering in Euclidean spaces

Clustering vectors

Most frequent words w over collection C of documents d

A fickle algorithm

We can't trust k -means: why?

Subsection 3

Distance instability

Nearest Neighbours

k -NEAREST NEIGHBOURS (k -NN).

Given:

- ▶ $k \in \mathbb{N}$
- ▶ a distance function $d : \mathbb{R}^n \times \mathbb{R}^n \rightarrow \mathbb{R}_+$
- ▶ a set $\mathcal{X} \subset \mathbb{R}^n$
- ▶ a point $z \in \mathbb{R}^n \setminus \mathcal{X}$,

find the subset $\mathcal{Y} \subset \mathcal{X}$ such that:

- $|\mathcal{Y}| = k$
- $\forall y \in \mathcal{Y}, x \in \mathcal{X} \quad (d(z, y) \leq d(z, x))$

- ▶ **basic problem in data science**
- ▶ pattern recognition, computational geometry, machine learning, data compression, robotics, recommender systems, information retrieval, natural language processing and more
- ▶ **Example:** Used in Step 2 of k-means:
assign points to closest centroid

[Cover & Hart 1967]

With random variables

- ▶ Consider 1-NN
- ▶ Let $\ell = |\mathcal{X}|$
- ▶ Distance function family $\{d^m : \mathbb{R}^n \times \mathbb{R}^n \rightarrow \mathbb{R}_+\}_m$
- ▶ For each m :
 - ▶ random variable Z^m with some distribution over \mathbb{R}^n
 - ▶ for $i \leq \ell$, random variable X_i^m with some distrib. over \mathbb{R}^n
 - ▶ X_i^m iid w.r.t. i , Z^m independent of all X_i^m
 - ▶ $D_{\min}^m = \min_{i \leq \ell} d^m(Z^m, X_i^m)$
 - ▶ $D_{\max}^m = \max_{i \leq \ell} d^m(Z^m, X_i^m)$

Distance Instability Theorem

- ▶ Let $p > 0$ be a constant
- ▶ If

$$\exists i \leq \ell \quad (d^m(Z^m, X_i^m))^p \text{ converges as } m \rightarrow \infty$$

then, for any $\varepsilon > 0$,

closest and furthest point are at about the same distance

Note “ $\exists i$ ” suffices since $\forall m$ we have X_i^m iid w.r.t. i

[Beyer et al. 1999]

Distance Instability Theorem

- ▶ Let $p > 0$ be a constant
- ▶ If

$$\forall i \leq \ell \lim_{m \rightarrow \infty} \text{Var} \left(\frac{(d^m(Z^m, X_i^m))^p}{\mathbb{E}((d^m(Z^m, X_i^m))^p)} \right) = 0$$

then, for any $\varepsilon > 0$,

$$\lim_{m \rightarrow \infty} \mathbb{P}(D_{\max}^m \leq (1 + \varepsilon) D_{\min}^m) = 1$$

Note “ $\exists i$ ” suffices since $\forall m$ we have X_i^m iid w.r.t. i

[Beyer et al. 1999]

Preliminary results

- ▶ Lemma. $\{B^m\}_m$ seq. of rnd. vars with finite variance and $\lim_{m \rightarrow \infty} \mathbb{E}(B^m) = b \wedge \lim_{m \rightarrow \infty} \text{Var}(B^m) = 0$; then

$$\forall \varepsilon > 0 \quad \lim_{m \rightarrow \infty} \mathbb{P}(\|B^m - b\| \leq \varepsilon) = 1$$

denoted $B^m \rightarrow_{\mathbb{P}} b$

- ▶ Slutsky's theorem. $\{B^m\}_m$ seq. of rnd. vars and g a continuous function; if $B^m \rightarrow_{\mathbb{P}} b$ and $g(b)$ exists, then $g(B^m) \rightarrow_{\mathbb{P}} g(b)$
- ▶ Corollary. If $\{A^m\}_m, \{B^m\}_m$ seq. of rnd. vars. s.t. $A^m \rightarrow_{\mathbb{P}} a$ and $B^m \rightarrow_{\mathbb{P}} b \neq 0$ then $\frac{A^m}{B^m} \rightarrow_{\mathbb{P}} \frac{a}{b}$

Proof

- $\mu_m = \mathbb{E}((d^m(Z^m, X_i^m))^p)$ independent of i
(since all X_i^m iid)
- $V_m = \frac{(d^m(Z^m, X_i^m))^p}{\mu_m} \rightarrow_{\mathbb{P}} 1$:
 - ▶ $\mathbb{E}(V_m) = 1$ (rnd. var. over mean) $\Rightarrow \lim_m \mathbb{E}(V_m) = 1$
 - ▶ Hypothesis of thm. $\Rightarrow \lim_m \text{Var}(V_m) = 0$
 - ▶ *Lemma* $\Rightarrow V_m \rightarrow_{\mathbb{P}} 1$
- $\mathbf{V}^m = (V_m \mid i \leq \ell) \rightarrow_{\mathbb{P}} \mathbf{1}$ (by iid)
- Slutsky's thm.* $\Rightarrow \min(\mathbf{V}^m) \rightarrow_{\mathbb{P}} \min(\mathbf{1}) = 1$
simy for max
- Corollary* $\Rightarrow \frac{\max(\mathbf{V}^m)}{\min(\mathbf{V}^m)} \rightarrow_{\mathbb{P}} 1$
- $\frac{D_{\max}^m}{D_{\min}^m} = \frac{\mu_m \max(\mathbf{V}^m)}{\mu_m \min(\mathbf{V}^m)} \rightarrow_{\mathbb{P}} 1$
- Result follows (defn. of $\rightarrow_{\mathbb{P}}$ and $D_{\max}^m \geq D_{\min}^m$)

A precision limit

- ▶ Closest and farthest point from z :
can't be told apart with precision $> \varepsilon$
- ▶ In real algorithms, often want “closest”
- ▶ Hope of telling apart closest from second-closest?

Loss of precision ε for $K \leq 10000$

Uniform(0, 1)

Normal(0, 1)

Exponential(1)

- ▶ Precision falls exponentially fast
- ▶ Generates algorithmic instability

When it applies

- ▶ iid random variables from any distribution
- ▶ Particular forms of correlation
e.g. $U_i \sim \text{Uniform}(0, \sqrt{i})$, $X_1 = U_1$, $X_i = U_i + (X_{i-1}/2)$ for $i > 1$
- ▶ Variance tending to zero
e.g. $X_i \sim \text{N}(0, 1/i)$
- ▶ Discrete uniform distribution on m -dimensional hypercube
for both data and query
- ▶ Computational experiments with k -means:
instability already with $n > 15$

...and when it doesn't

- ▶ Complete linear dependence on all distributions
can be reduced to NN in 1D
- ▶ Exact and approximate matching
query point = (or \approx) data point
- ▶ Query point in a well-separated cluster in data
- ▶ Implicitly low dimensionality
project; but NN must be stable in lower dim.

Subsection 4

MP formulations

Why?

- ▶ With k-means being so fast, why bother with MP?
- ▶ Principle:
changing an MP is easier than changing an algorithm
- ▶ Side constraints
e.g. clusters are spheres, or other shapes
- ▶ Clustering subproblems
e.g. assign resources subject to optimal clustering
- ▶ MP delivers a bound
“can’t do better than bound” guarantee

MP formulation

$$\left. \begin{array}{ll} \min_{x,y,s} & \sum_{i \leq n} \sum_{j \leq k} \|p_i - y_j\|_2^2 x_{ij} \\ \forall j \leq k & \frac{1}{s_j} \sum_{i \leq n} p_i x_{ij} = y_j \\ \forall i \leq n & \sum_{j \leq k} x_{ij} = 1 \\ \forall j \leq k & \sum_{i \leq n} x_{ij} = s_j \\ \forall j \leq k & y_j \in \mathbb{R}^m \\ & x \in \{0, 1\}^{nk} \\ & s \in \mathbb{N}^k \end{array} \right\} \text{(MSSC)}$$

MINLP: nonconvex terms; continuous, binary and integer variables

Reformulation

The (MSSC) formulation has the same optima as:

$$\left. \begin{array}{ll} \min_{x,y,P} & \sum_{i \leq n} \sum_{j \leq k} P_{ij} x_{ij} \\ \forall i \leq n, j \leq k & \|p_i - y_j\|_2^2 \leq P_{ij} \\ \forall j \leq k & \sum_{i \leq n} p_i x_{ij} = \sum_{i \leq n} y_j x_{ij} \\ \forall i \leq n & \sum_{j \leq k} x_{ij} = 1 \\ \forall j \leq k & y_j \in ([\min_{i \leq n} p_{ih}, \max_{i \leq n} p_{ih}] \mid h \leq k) \\ & x \in \{0, 1\}^{nk} \\ & P \in [0, P^U]^{nk} \end{array} \right\}$$

- ▶ The only nonconvexities are *products of binary by continuous bounded variables*

Products of binary and continuous vars.

- ▶ Suppose term xy appears in a formulation
- ▶ Assume $x \in \{0, 1\}$ and $y \in [0, 1]$ is bounded
- ▶ means “either $z = 0$ or $z = y$ ”
- ▶ Replace xy by a new variable z
- ▶ Adjoin the following constraints:

$$\begin{aligned}z &\in [0, 1] \\y - (1 - x) &\leq z \leq y + (1 - x) \\-x &\leq z \leq x\end{aligned}$$

- ▶ \Rightarrow Everything's linear now!

[Fortet 1959]

Products of binary and continuous vars.

- ▶ Suppose term xy appears in a formulation
- ▶ Assume $x \in \{0, 1\}$ and $y \in [y^L, y^U]$ is bounded
- ▶ means “either $z = 0$ or $z = y$ ”
- ▶ Replace xy by a new variable z
- ▶ Adjoin the following constraints:

$$\begin{aligned} z &\in [\min(y^L, 0), \max(y^U, 0)] \\ y - (1 - x) \max(|y^L|, |y^U|) &\leq z \leq y + (1 - x) \max(|y^L|, |y^U|) \\ -x \max(|y^L|, |y^U|) &\leq z \leq x \max(|y^L|, |y^U|) \end{aligned}$$

- ▶ \Rightarrow Everything's linear now!

[L. et al. 2009]

MSSC is a convex MINLP

$$\begin{aligned}
 & \min_{x,y,P,\chi,\xi} \quad \sum_{i \leq n} \sum_{j \leq k} \chi_{ij} \\
 \forall i \leq n, j \leq k \quad & 0 \leq \chi_{ij} \leq P_{ij} \\
 \forall i \leq n, j \leq k \quad & P_{ij} - (1 - x_{ij})P^U \leq \chi_{ij} \leq x_{ij}P^U \\
 \forall i \leq n, j \leq k \quad & \|p_i - y_j\|_2^2 \leq P_{ij} \quad \leftarrow \text{convex} \\
 \forall j \leq k \quad & \sum_{i \leq n} p_i x_{ij} = \sum_{i \leq n} \xi_{ij} \\
 \forall i \leq n, j \leq k \quad & y_j - (1 - x_{ij}) \max(|y^L|, |y^U|) \leq \xi_{ij} \leq y_j + (1 - x_{ij}) \max(|y^L|, |y^U|) \\
 \forall i \leq n, j \leq k \quad & -x_{ij} \max(|y^L|, |y^U|) \leq \xi_{ij} \leq x_{ij} \max(|y^L|, |y^U|) \\
 \forall i \leq n \quad & \sum_{j \leq k} x_{ij} = 1 \\
 \forall j \leq k \quad & y_j \in [y^L, y^U] \\
 & x \in \{0, 1\}^{nk} \\
 & P \in [0, P^U]^{nk} \\
 & \chi \in [0, P^U]^{nk} \\
 \forall i \leq n, j \leq k \quad & \xi_{ij} \in [\min(y^L, 0), \max(y^U, 0)]
 \end{aligned}$$

y_j, ξ_{ij}, y^L, y^U are vectors in \mathbb{R}^m

How to solve it

- ▶ cMINLP is **NP-hard**

- ▶ Algorithms:

 - ▶ *Outer Approximation* (OA)

 - ▶ *Branch-and-Bound* (BB)

- ▶ Best (open source) solver: BONMIN

- ▶ Another good (commercial) solver: KNITRO

- ▶ *With $k = 2$, unfortunately...*

Cbc0010I After 8300 nodes, 3546 on tree, 14.864345 best solution,
best possible 6.1855969 (32142.17 seconds)

- ▶ *Interesting feature: the bound*

guarantees we can't do better than *bound*
all BB algorithms provide it

Couple of things left to try

- ▶ Approximate ℓ_2 by ℓ_1 norm
 ℓ_1 is a linearizable norm
- ▶ Randomly project the data
lose dimensions but keep approximate shape

Linearizing convexity

- ▶ Replace $\|p_i - y_j\|_2^2$ by $\|p_i - y_j\|_1$

- ▶ **Warning:** optima will change

but still within “clustering by distance” principle

$$\forall i \leq n, j \leq k \quad \|p_i - y_j\|_1 = \sum_{a \leq d} |p_{ia} - y_{ja}|$$

- ▶ Replace each $|\cdot|$ term by new vars. $Q_{ija} \in [0, P^U]$

Adjust P^U in terms of $\|\cdot\|_1$

- ▶ Adjoin constraints

$$\forall i \leq n, j \leq k \quad \sum_{a \leq d} Q_{ija} \leq P_{ij}$$

$$\forall i \leq n, j \leq k, a \leq d \quad -Q_{ija} \leq p_{ia} - y_{ja} \leq Q_{ija}$$

- ▶ Obtain a MILP

Most advanced MILP solver: CPLEX

CPLEX

Subsection 5

Random projections again

Works on the MSSC MP formulation too!

$$\left. \begin{array}{l}
 \min_{x,y,s} \sum_{i \leq n} \sum_{j \leq d} \|T p_i - T y_j\|_2^2 x_{ij} \\
 \forall j \leq d \quad \frac{1}{s_j} \sum_{i \leq n} T p_i x_{ij} = T y_j \\
 \forall i \leq n \quad \sum_{j \leq d} x_{ij} = 1 \\
 \forall j \leq d \quad \sum_{i \leq n} x_{ij} = s_j \\
 \forall j \leq d \quad y_j \in \mathbb{R}^m \\
 \quad \quad \quad x \in \{0, 1\}^{nd} \\
 \quad \quad \quad s \in \mathbb{N}^d
 \end{array} \right\}$$

where T is a $k \times m$ random projector
 replace $T y$ by y'

Works on the MSSC MP formulation too!

$$\left. \begin{array}{ll} \min_{x, y', s} & \sum_{i \leq n} \sum_{j \leq d} \|T p_i - y'_j\|_2^2 x_{ij} \\ \forall j \leq d & \frac{1}{s_j} \sum_{i \leq n} T p_i x_{ij} = y'_j \\ \forall i \leq n & \sum_{j \leq d} x_{ij} = 1 \\ \forall j \leq d & \sum_{i \leq n} x_{ij} = s_j \\ \forall j \leq d & y'_j \in \mathbb{R}^k \\ & x \in \{0, 1\}^{nd} \\ & s \in \mathbb{N}^d \end{array} \right\} \text{(MSSC')}$$

- ▶ where $k = O(\frac{1}{\epsilon^2} \ln n)$
- ▶ less data, $|y'| < |y| \Rightarrow$ get solutions faster
- ▶ Yields smaller cMINLP
