12 We propose a variant of public announcement logic for asynchronous systems. To capture asynchrony, we introduce two different modal operators for sending and receiving messages. 13 The natural approach to defining the semantics leads to a circular definition, but we describe 14 two restricted cases in which we solve this problem. The first case requires the Kripke model 15 representing the initial epistemic situation to be a finite tree, and the second one only allows 16 17 announcements from the existential fragment. After establishing some validities, we study the model checking problem and the satisfiability problem in cases where the semantics is 18 19 well-defined, and we provide several complexity results.

20 1. Introduction

21 Asynchrony plays a central role in distributed systems such as robotic rescue teams, smart cities, autonomous vehicles, etc. In such systems, there may be an unpredictable delay 22 23 between sending and receiving messages, and there is not always access to a centralized clock. Recently, with the proliferation of multi-agent systems (MAS), where independent 24 agents interact, communicate, and make decisions under imperfect information, modelling 25 the evolution of knowledge as informative events occur has become increasingly important 26 for both verification and design. For instance, it is often crucial to know whether an agent 27 has received some information, so it would be highly desirable to be able to analyse 28 messages such as 'agent a knows that agent b received message m,' i.e., we want to 29 model 30

messages with epistemic content, (1)

and because we are considering automated systems where agents do not lie, make
 logical mistakes, or have inaccurate factual information (for instance autonomous vehicles
 communicating about their position), we also make the classic assumption that

34

messages are true when they are sent. (2)

Public Announcement Logic (PAL) (Plaza 2007) is one of the first and most influential 35 proposals for modelling the relationship between knowledge and announcements. In PAL, 36 true announcements are made to a group of agents. This logic later led to the powerful 37 and much studied dynamic epistemic logic (DEL) (van Ditmarsch et al. 2007), which can 38 describe more complex forms of communication, such as semi-private announcements, 39 private announcements and much more. However, both these logics assume synchronicity: 40 In PAL messages are immediately received by all agents at the same time, as soon as 41 42 they are sent and in DEL agents may perceive events differently, but events immediately change the epistemic state of agents as soon as they occur. In asynchronous settings, 43 44 however, messages are not delivered instantly, and agents may receive them at different points in time, making PAL intrinsically unfit for reasoning about such settings. This 45 fact becomes even more evident when we consider that in PAL, every announcement 46 immediately leads to *common knowledge*, while common knowledge is not achievable in 47 asynchronous systems (Halpern and Moses 1990; Moses and Tuttle 1988). The only work 48 we know of considering how DEL can capture asynchrony is (Dégremont et al. 2011), 49 but in this logic an agent can only consider possible 'future' events if they do not change 50 her epistemic state. This is related to the principle of inertia (Braüner et al. 2016; van 51 Lambalgen 2010), which states that in absence of any observation, one assumes that 52 53 nothing has happened. This assumption is natural in contexts, where agents believe that they can observe all events at the time of their occurrence. In asynchronous systems 54 55 however, agents should know that even when they do not observe anything, or when they do not receive any messages, it is possible that messages are being sent and received by 56 other agents. Therefore the inertia principle does not apply in our setting, and agents 57 should be able to 58

imagine possible pending messages. (3)

59 Our aim is to propose a logic in the spirit of PAL for reasoning about (1) epistemic 60 messages in asynchronous systems, (2) that are true at the time of announcement and 61 where (3) agents can imagine messages that have been sent but not yet received.

Because this is an ambitious endeavour, we make a few assumptions to start as simply as possible:

Broadcasts: all messages are sent to every agent

64 **External source:** messages are emitted by an external, omniscient source

FIFO: messages are received in the order they are sent.

65 The first assumption comes from PAL, and is natural in the context of smart cities for instance, where autonomous vehicles broadcast their current position or direction. The 66 second one is a choice made to simplify the syntax by not having to model the origin of 67 announcements, as in PAL. Announcements from an external, omniscient source can in 68 some cases be used to model messages broadcast by agents within the system, in particular, 69 an omniscient outside agent broadcasting that agent a knows φ is in many situations 70 equivalent to agent a broadcasting φ to the other agents within the system. This captures 71 the fact that in order for an agent within the system to make a true announcement, she 72 should know that the announcement is true before she broadcasts it. Thus upon receiving 73 an announcement made by agent a, another agent learns both the announcement and 74

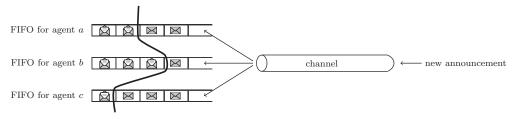

Fig. 1. Agent architecture.

the fact that *a* knows it, modelled within the framework where announcements come from an external source by the announcement of $K_a \psi$ (K_a being the classic knowledge operator of epistemic logics, see for instance Fagin *et al.* (2004)). However, depending on assumptions about the agents' epistemic and reasoning capacities, this way of modelling agents' announcements may not be completely faithful to the real situation. We discuss this issue briefly in the future work section.

Concerning the last assumption, FIFO is a simple but classic scheme of communication
 in asynchronous systems (see for instance Brand and Zafiropulo (1983); Chambart and
 Schnoebelen (2008); Yu and Gouda (1982)).

Figure 1 depicts the architecture of such a system with three autonomous agents receiving messages from a public channel and reading them when they are ready to process them. To represent the fact that agents read messages in the order they were sent, we provide each one with a private FIFO channel. Each copy receives the same messages from the public channel, in the order in which they are announced, but the moment at which these messages are read differs from one agent to another.

- In PAL, messages are received at the same time they are sent, and thus the announcement
 operator combines both sending and receiving. In contrast, in our setting, messages are
 not received immediately and they may be received at different times by different agents.
 The syntax reflects this aspect by providing both a sending operator, which adds new
 messages to the public channel, and a receiving operator for each agent, which allows her
 to read the first message in her FIFO queue that she has not read yet. Thus, in our logic,
 we provide the following modal constructions:
- 97 $\langle \psi \rangle \varphi$, which means ' ψ is currently true, and after its announcement, φ holds;'
- 98 $\bigcirc_a \varphi$, which means 'after agent *a* reads the next announcement, φ holds;'
- 99 $K_a \varphi$, which means 'agent *a* knows that φ holds.'

Interestingly, the natural semantics for this logic presents a challenging problem of 100 circular definition: In order to define the truth of epistemic formulas, we classically 101 102 quantify over the set of all states that the agent considers possible, where states include the current content of the public channel and pointers to the last message read by each 103 agent. But some states are not *consistent* and must not be considered: intuitively a state 104 is consistent if the announcements it contains were true at the time they were made. 105 Therefore, defining consistent states requires defining the truth of formulas, and vice 106 versa. PAL presents a similar circularity, as the definition of the update of a model by 107 an announcement and the definition of the truth values are mutually dependent, thus 108 this phenomenon is not inherent to the asynchronous setting. However, only asynchrony 109

110 makes it a problem. Indeed in PAL a simple definition by mutual induction is possible. In an asynchronous setting, however, agents do not know what or how many messages other 111 agents have received; in particular, an agent may consider it possible that some formula 112 has been announced that is bigger than all those that have actually been announced, 113 which makes a mutual induction impossible for lack of a decreasing quantity. This 114 circularity problem is inherent in the asynchronous setting, and is independent from the 115 assumptions of broadcasts, external source and FIFO described above. It only depends 116 117 on the assumptions that announcements can talk about knowledge (1), that they must be true (2) and that agents can imagine pending messages (3). 118

119 We partially solve the issue by defining three restricted cases in which we manage to avoid circularity. The first one requires the Kripke model representing the initial 120 epistemic situation to be a finite tree; the second one only allows announcements from 121 the existential fragment of our logic, and the third one makes the assumption that only a 122 bounded number of announcements can be made during each time unit (a strong form 123 of non-Zeno assumption), and that agents have access to a global clock. In the second 124 case, the semantics is defined thanks to an application of the Knaster-Tarski fixed point 125 theorem (Tarski 1955). 126

We then discuss some properties of our logics, compare them to PAL, and establish some validities that hold whenever the semantics is well-defined; we also study the model checking problem for our logic and establish the following complexity results:

Restrictions	Complexity of model checking
Propositional announcements	PSPACE -complete
Finite tree initial models	in PSPACE
Announcements from the existential fragment	in Exptime, Pspace -hard

Finally, we study the satisfiability problem in the case of propositional announcements,
and we establish that it is NEXPTIME -complete.

The paper is organized as follows. In Section 2, we recall (synchronous) PAL. In Section 3, we present our logic, and discuss the circularity problem that arises from the definition of the semantics, and present an example to illustrate the logic. In Section 4, we exhibit cases where it can be solved. We then present some properties in Section 5 (a comparison with PAL and some validities), we study the model checking problem in Section 6 and the satisfiability problem in Section 7. Finally, we discuss related work in Section 8 and future work in Section 9.

140 This paper is an extended version of Knight *et al.* (2015). Section 7 is completely new 141 material. The other sections are based on the older version of this paper but include more 142 details, improvements and clarifications.

143 2. Background: Public Announcement Logic

130

144 In this section, we recall PAL (Plaza 2007), the classic logic for synchronous public 145 announcements. Let \mathcal{AP} be a countable infinite set of *atomic propositions*, and let Ag be 146 a finite set of *agents*.

(a)
$$\underbrace{u:\neg p} \xleftarrow{a, b} \underbrace{v:p} \xleftarrow{w:p} (b)$$

Fig. 2. A Kripke model and an updated Kripke model.

147 **Definition 2.1.** The syntax of PAL is given by the following grammar:

$$\varphi ::= p \mid (\varphi \land \varphi) \mid \neg \varphi \mid K_a \varphi \mid \langle \varphi \rangle_{\text{PAL}} \varphi,$$

148 where p ranges over \mathcal{AP} and a ranges over Ag.

149 The intuitive meaning of the last two operators is the following: $K_a \varphi$ means that agent *a* 150 knows φ , and $\langle \psi \rangle_{PAL} \varphi$ means that ψ is true and after ψ has been publicly announced and 151 publicly received by all the agents (meaning that all agents know that each agent received 152 the message), φ holds. We define the following usual abbreviations: $\bot := p \land \neg p, \top := \neg \bot$, 153 $\varphi \lor \varphi' := \neg(\neg \varphi \land \neg \varphi')$ and the dual of the knowledge modality, $\hat{K}_a \varphi := \neg K_a \neg \varphi$, which 154 reads as 'agent *a* considers it possible that φ holds.'

The semantics of PAL relies on classic Kripke models and the *possible worlds* semantics, widely used in logics of knowledge (Fagin *et al.* 2004).

157 **Definition 2.2.** A Kripke model is a tuple $\mathcal{M} = (W, \{\rightarrow_a\}_{a \in Ag}, \Pi)$, where:

- 158 W is a non-empty finite set of worlds,
- 159 for each $a \in Ag$, $\rightarrow_a \subseteq W \times W$ is an accessibility relation for agent a,
- 160 $\Pi: W \to 2^{\mathcal{AP}}$ is a valuation on worlds.

161 A pointed model (\mathcal{M}, w) is a model \mathcal{M} with a specified world w. For the sake of 162 generality, we allow arbitrary relations and not only equivalence relations as traditional 163 in epistemic logic (Fagin *et al.* 2004; van Ditmarsch *et al.* 2007).[†]

Example 2.1. Let us consider the Kripke model of Figure 2a, where w, u and v are worlds, a and b are agents and p is an atomic proposition. The arrows represent the agents' accessibility relations. At world w, agent a considers u and v possible, and agent b considers only world v possible. Now assume that p is announced in (\mathcal{M}, w) . This is possible, as p holds in w. As a result of this announcement, all agents know that p holds, and thus the resulting epistemic situation is obtained by removing all worlds, where pdoes not hold, i.e., u. This updated model is represented in Figure 2b.

- The update of a Kripke model by an announcement and the semantics of PAL are definedby mutual induction.
- 173 **Definition 2.3.** The update of a Kripke model \mathcal{M} with an announcement ψ is the Kripke 174 model $\mathcal{M}^{\psi} = (W^{\psi}, \{\rightarrow_a^{\psi}\}_{a \in Ag}, \Pi^{\psi})$, where
- 175 $W^{\psi} = \{ u \in W \mid \mathcal{M}, u \models \psi \};$
- 176 $\longrightarrow_{a}^{\psi} = \longrightarrow_{a} \cap (W^{\psi} \times W^{\psi})$ for all agents *a*;
- 177 Π^{ψ} is the function Π restricted to W^{ψ} ,

[†] This allows for alternative semantics of knowledge such as S4 (Hintikka 1962), S4.2 (Lenzen 1978), S4.3 (van der Hoek 1990), S4.4 (Kutschera 1976), KD45 for beliefs (Fagin *et al.* 2004), etc.

 $\mathcal{M}, w \models \langle \psi \rangle_{_{\mathsf{PAI}}} \varphi \quad \text{if} \mathcal{M}, w \models \psi \text{ and } \mathcal{M}^{\psi}, w \models \varphi.$

180 Observe that the definition by structural induction on φ is sound: defining the semantics 181 of $\langle \psi \rangle_{PAL} \varphi$ requires having defined the update of a Kripke model by announcement ψ , 182 which only requires having defined the semantics of ψ , a subformula of φ .

- **Example 2.2.** Let \mathcal{M} be the model of Figure 2a. We have $\mathcal{M}, w \models \langle p \rangle_{PAL} K_a p$. Indeed, the announcement *p* is true, that is $\mathcal{M}, w \models p$, and $\mathcal{M}^p, w \models K_a p$. Note that \mathcal{M}^p is the model of Figure 2b.
- The model-checking problem of PAL is P -complete (the membership in P is established in Benthem (2011) and P-hardness in Schnoebelen $(2002)^{\ddagger}$) and the satisfiability problem for PAL is PSPACE -complete (Lutz 2006). A tableau proof system for PAL is provided in Baltag *et al.* (2008).
- 190 3. Asynchronous broadcast logic

In this section, we present our framework for reasoning about asynchronous epistemic announcements in a public channel. As in Section 2, \mathcal{AP} is a countable infinite set of atomic propositions, and Ag is a finite set of agents. For pedagogical reasons, we first introduce models, then the syntax and finally the semantics of our logic, even though by doing so we need to refer to the language before we formally define it.

196 3.1. *Models*

Agents start with an initial state of knowledge of the world, which is modelled by an initial 197 pointed epistemic model, or Kripke model. Then true announcements are made by some 198 external entity, and sent in the public channel. The whole sequence of announcements that 199 have been made up to the present moment is modelled as a sequence of formulas from 200 201 our logic, whose syntax we introduce later in Section 3.2. Agents read these messages independently, possibly at different times, but in FIFO order. To represent which messages 202 203 each agent has already read, and thus which ones remain to be read, we simply map each agent to the number of announcements she has read. Such a mapping is called a *cut*. 204

205 3.1.1. Initial Kripke model. An initial model is given as a Kripke model $\mathcal{M} = (W, \{\rightarrow_a\}_{a \in Ag}, \Pi)$, as defined in Definition 2.2. It represents the initial knowledge of agents before any announcements are made, and it corresponds to the notion of initial

[‡] Epistemic logic is an extension of the fragment of CTL with only the next operators AX and EX, proven to be P-hard.

208 knowledge in (Raynal 2013), p. 5. In practice, (\mathcal{M}, w) is directly provided by the modeller 209 or inferred from what agents perceive (Balbiani *et al.* 2013; Gasquet *et al.* 2015).

3.1.2. Announcements. We consider that, in a given scenario, not every formula may be
announced, but rather that there is a certain set of relevant announcements. Furthermore,
we allow the number of times an announcement can be made to be bounded. To
represent this, we define the notion of announcement protocols (Asynchronous Broadcast
Logic (ABL) is the language defined in Section 3.2).

- 215 **Definition 3.1.** An *announcement protocol* is a multiset of formulas in ABL, where the 216 multiplicity of an element ψ is either an integer or ∞ .
- **Example 3.1.** The reader may imagine a card game where it is only possible to announce 'agent *a* has a heart card' once and 'agent *a* does not know whether agent *b* has a heart card or not' twice. We let the proposition \heartsuit_a mean 'agent *a* has a heart card,' and define the announcement protocol to be $\{\{\heartsuit_a, \hat{K}_a \heartsuit_b \land \hat{K}_a \neg \heartsuit_b, \hat{K}_a \neg \heartsuit_b\}\}$.

Given an announcement protocol \mathcal{A} , we denote by Seq(\mathcal{A}) the set of finite sequences $\sigma = [\varphi_1, \dots, \varphi_k]$ such that the multiset $\{\{\varphi_1, \dots, \varphi_k\}\}$ is a submultiset of \mathcal{A} . We define the size of a sequence σ as $|\sigma| := \sum_{i=1}^k |\varphi_i|$. For $\sigma, \sigma' \in$ Seq(\mathcal{A}), we write $\sigma \leq \sigma'$ if σ is a prefix of σ' . The sequence $\sigma|_k$ is the prefix of σ of length k. Given a formula φ and a sequence of formulas $\sigma, \varphi::\sigma$ (resp. $\sigma::\varphi$) is the sequence obtained by adding φ at the beginning (resp. at the end) of σ .

3.1.3. *States.* We now define the set of possible states of the models in which the formulasof our logic will be evaluated.

229 **Definition 3.2.** Let \mathcal{M} be an initial model and \mathcal{A} an announcement protocol. We define 230 the set of *possible states* $S_{\mathcal{M},\mathcal{A}}$ as follows:

$$\mathcal{S}_{\mathcal{M},\mathcal{A}} = \{ (w,\sigma,c) \mid w \in W, \sigma \in \mathsf{Seq}(\mathcal{A}) \text{ and } c : Ag \to \{0,\ldots,|\sigma|\} \}.$$

The first element of a state represents the world the system is in. The second element is the list of messages that have already been announced. The last element, c, is called a *cut*, and for each $a \in Ag$, c(a) is the number of announcements of σ that agent a has received so far. Given two cuts c and c', we write c < c' if for all a, $c(a) \leq c'(a)$ and there exists b such that c(b) < c'(b): in other words, c < c' if all agents have received at least as many messages in c' as in c, and at least one agent received strictly more messages in c'. Typical elements of $S_{M,A}$ are denoted S, S', etc.

Example 3.2. Consider the state $S = (w, [\varphi, \psi, \chi], c)$, where c(a) = 2 and c(b) = 1. *S* represents the situation where in initial world *w*, the sequence $[\varphi, \psi, \chi]$ of formulas has been announced, agent *a* has received φ and ψ , and agent *b* has only received φ . Only χ remains in the queue of *a* and has not been read yet, and only ψ and χ remain in the queue of *b*. We represent *S* as follows:

$$w \begin{array}{c} \varphi & \psi & \chi \\ & \widehat{\mathbf{x}} & \widehat{\mathbf{x}} & \widehat{\mathbf{x}} \\ b : & \widehat{\mathbf{x}} & \widehat{\mathbf{x}} & \widehat{\mathbf{x}} \end{array}$$

243 and we may also write $S = (w, [\varphi, \psi, \chi], \stackrel{a}{b} \xrightarrow{b} 1)$.

Example 3.3. Consider the state $S = (w, \epsilon, \mathbf{0})$, where ϵ denotes the empty sequence of formulas and $\mathbf{0}$ is the function that assigns 0 to all agents. S represents an initial world w in which no announcement has been made (and therefore no announcement has been received either). It can be represented as follows:

$$w \begin{array}{c} a:\\ b:\\ w \end{array} \Big|_{w^{o}} w^{e^{ss}a^{ge^{s}}}$$

Example 3.4. State $S = (w, [\varphi, \chi], \mathbf{0})$, which represents the situation where in initial world w, φ and χ have successively been announced, but neither agent *a* or agent *b* received any announcement yet. We depict it as follows:

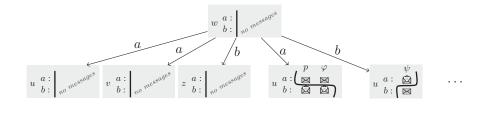

$$w \begin{array}{c} a: \\ b: \\ \hline \bowtie \end{array} \begin{array}{c} \varphi & \chi \\ \hline \bowtie & \bowtie \\ \hline \bowtie & \bowtie \end{array}$$

3.1.4. Consistent states. Definition 3.2 allows for all combinations of worlds, sequences of announcements allowed by the announcement protocol, and cuts. This definition is an overapproximation of the set of states we want to consider: indeed, because announcements must be true, some of the states in S are *inconsistent*. For example, suppose that w is a world in \mathcal{M} where p does not hold. Because only true announcements can be made, p cannot be announced in world w, and thus the state $(w, [p], \mathbf{0})$ is inconsistent.

Example 3.5. Let us consider the following initial model, where w, u, v and z are worlds, *a* and *b* are agents and *p* is a proposition. The arrows represent the agents' accessibility relations, before any announcements have been made. So at world *w*, agent *a* considers *u* and *v* possible, and agent *b* considers world *z* possible.

Now assuming that the announcement protocol \mathcal{A} contains p, φ and ψ , a partial depiction of the asynchronous model $\mathcal{M} \otimes \mathcal{A}$ is below. We depict the states w, u, v, and z where no announcement has been made, as well as copies of u where two different sequences of announcements have been made, and received in one state by agent b and in a different state by agent *a*. Of course, the entire model $\mathcal{M} \otimes \mathcal{A}$ is infinite so we do not depict all the states here.

267 State $\begin{bmatrix} u & b \\ b & e \end{bmatrix}$ is not consistent because p has been announced even though p is not 268 true in u. This notion of inconsistency is the source of the circularity problem, as we 269 discuss in Section 3.4. For now, we define the relations that capture which states an agent 270 considers possible before removal of inconsistent ones.

3.1.5. *Pre-accessibility relation and asynchronous pre-model*. We now define, for each agent, a *pre-accessibility relation* that does not yet take consistency into account, but is only based on the agents' accessibility relations in the initial model, and the messages it has already read.

- **Definition 3.3.** The *pre-accessibility relation* for agent *a*, written R_a , is defined as follows: given $S = (w, \sigma, c)$ and $S' = (w', \sigma', c')$, we have SR_aS' if:
- 277 1. $w \rightarrow_a w'$, and

278 2.
$$\sigma|_{c(a)} = \sigma'|_{c'(a)}$$
.

The first clause simply says that for S' to be considered possible by a when in S, world w' 279 280 must be considered possible by a from w. The second clause says that agent a is aware of, and only aware of, messages that she has received: therefore she can only consider possible 281 282 states where she has received exactly the same messages. Then, because the principle of inertia does not apply to the asynchronous setting, she can imagine any possible sequence 283 of pending announcements, as long as it is compatible with the announcement protocol. 284 Also, as she has no information about what messages the other agents have received, c'(b)285 can be anything if $b \neq a$: agent a considers it possible that b received more, or fewer, 286 messages than she actually has. Note that the second clause also implies c(a) = c'(a). 287

Given an initial model \mathcal{M} and an announcement protocol \mathcal{A} , we define the *asynchronous pre-model* $\mathcal{M} \otimes \mathcal{A} := (S_{\mathcal{M},\mathcal{A}}, \{R_a\}_{a \in Ag})$, where $S_{\mathcal{M},\mathcal{A}}$ is the set of possible states, and for $a \in Ag$, R_a is the pre-accessibility relation for agent a.

291 3.2. *Language*

We now introduce the syntax of our logic, which we call *Asynchronous Broadcast Logic*, or ABL for short. Note that we do not use the term 'public announcement' in the name of our logic as it has a strong synchronous connotation: public announcements are often thought of as becoming common knowledge the moment they are made.

296 **Definition 3.4 (Syntax).** The set of ABL-formulas is given by the following grammar:

$$\varphi ::= p \mid (\varphi \land \varphi) \mid \neg \varphi \mid K_a \varphi \mid \langle \varphi \rangle \varphi \mid \bigcirc_a \varphi,$$

297 where *p* ranges over \mathcal{AP} and *a* ranges over Ag.

The intuitive meaning of the last three operators is the following: $K_a \varphi$ means that agent *a* knows φ , $\langle \psi \rangle \varphi$ means that ψ is true and after ψ has been put on the public channel, φ holds, and $\bigcirc_a \varphi$ means that agent *a* has a pending message, and after she has received and read it, φ holds. We define the dual of the announcement operator: $[\psi]\varphi := \neg \langle \psi \rangle \neg \varphi$, meaning that if ψ is true, then φ holds after its announcement. $|\varphi|$ is the length of φ , and we denote by *propositional formula* a formula that uses no modalities, i.e., containts no occurrences of K_a , $\langle \varphi \rangle$, or \bigcirc_a .

In (synchronous) PAL (see Definition 2.1), the operator $\langle \psi \rangle_{PAL}$ captures both the broadcast and the reception of an announcement ψ , because in the synchronous setting, sending and reception occur simultaneously. In our asynchronous setting, not only can sending and reception occur at different times, but also different agents may receive the same message at different times. Therefore, we capture the broadcast of a formula ψ with operator $\langle \psi \rangle$, while agent *a*'s reception of a broadcasted formula is captured by the operator \bigcirc_a .

312 3.3. *Truth conditions*

For the rest of the section, we fix an initial model \mathcal{M} and an announcement protocol \mathcal{A} . As discussed in Section 3.1.4, some possible states from Definition 3.2 are inconsistent, because they contain announcements that were not true at the time they were announced. Also, because agents should not consider inconsistent states possible, we described how defining consistency is necessary to define the semantics of the knowledge operator, which in turn is necessary to define the consistency of states that contain epistemic announcements, hence a circularity problem.

We describe in Figure 3, the definition of consistency (represented with symbol \checkmark) as well as truth conditions for our logic. This definition is circular, and therefore the semantics as presented here is not well-founded, although it conveys the intended meaning of our operators. In the next section, we will describe restricted cases in which we can provide a semantics that is well-defined.

The intuitive meaning of $(w, \sigma, c) \models \checkmark$ is that the state (w, σ, c) is consistent, that is, all announcements in σ were true when they were made. The first clause is obvious: the initial state where no announcement has been made is consistent. The second clause gives two possibilities for a state to be consistent. Either there was an earlier consistent state (w, σ, c') in which some agents received some already announced formulas, increasing the cut from c' to c, or a new, *true* announcement ψ has been made from an earlier consistent state, extending the history from σ' to $\sigma'::\psi$.

For the formulas, the first three clauses are straightforward. The fourth clause says that agent *a* knows φ if φ holds in all consistent states that she considers possible. The fifth clause says that $\langle \psi \rangle \varphi$ holds in a state *S* if ψ can be announced (it is true in *S*), and φ

Truth conditions for consistency:

 $(w, \epsilon, \mathbf{0}) \models \checkmark$ (always) $(w, \sigma, c) \models \checkmark$ if there is c' < c s.t. $(w, \sigma, c') \models \checkmark$, or $\sigma = \sigma' :: \psi, (w, \sigma', c) \in \mathcal{S}_{\mathcal{M}, \mathcal{A}},$ $(w, \sigma', c) \models \checkmark$ and $(w, \sigma', c) \models \psi$ Truth conditions for formulas: $(w, \sigma, c) \models p$ if $p \in \Pi(w)$ $(w, \sigma, c) \models (\varphi_1 \land \varphi_2)$ if $(w, \sigma, c) \models \varphi_1$ and $(w, \sigma, c) \models \varphi_2$ $(w, \sigma, c) \models \neg \varphi$ if $(w, \sigma, c) \not\models \varphi$ $(w, \sigma, c) \models K_a \varphi$ if for all S' s.t. $(w, \sigma, c)R_aS'$ and $S' \models \checkmark, S' \models \varphi$ $(w, \sigma, c) \models \langle \psi \rangle \varphi$ $\sigma::\psi \in \mathsf{Seq}(\mathcal{A}), \ (w,\sigma,c) \models \psi \text{ and } (w,\sigma::\psi,c) \models \varphi$ if $c(a) < |\sigma|$ and $(w, \sigma, c^{+a}) \models \varphi$ $(w, \sigma, c) \models \bigcirc_a \varphi$ if where $c^{+a}(b) = \begin{cases} c(b) & \text{if } b \neq a \\ c(b) + 1 & \text{if } b = a \end{cases}$

Fig. 3. Consistency and semantics.

holds in the state obtained by adding ψ to the public channel. The last clause says that $\bigcirc_a \varphi$ holds if agent *a* has at least one unread announcement in the channel, and φ holds after she reads the first unread message.

338 3.4. *Circularity*

By observing the truth conditions for consistency and for formulas in Figure 3, one can see that defining whether a state is consistent requires one to define whether an announcement can be made, and this requires the semantics of our logic to be defined. But to define the semantics of the knowledge operators, we need to define which *consistent* states are considered possible by the agent, which requires us to define which states are consistent, hence the circularity.

Let us consider the following example, where $Ag = \{a\}$. Let the initial model be $\mathcal{M} = \{W, \rightarrow_a, \Pi\}$ where $W = \{w\}, \rightarrow_a = \{(w, w)\}$ and $\Pi(w) = \emptyset$, and let the announcement protocol be $\mathcal{A} = \{\{K_ap\}\}$. According to Figure 3, we have: $(w, [K_ap], \mathbf{0}) \models \checkmark$ iff $(w, \epsilon, \mathbf{0}) \models K_ap$. But, as $(w, \epsilon, \mathbf{0})R_a(w, [K_ap], \mathbf{0})$, the definition of the truth value of $(w, \epsilon, \mathbf{0}) \models K_ap$ depends on the truth value of $(w, [K_ap], \mathbf{0}) \models \checkmark$. To sum up, the definition of $(w, [K_ap], \mathbf{0}) \models \checkmark$ depends on itself.

The circularity problem depends on assumptions (1), (2) and (3) from the introduction:

351

- 352 Announcements can be epistemic
- 353 Announcements are true
- 354 Agents can imagine pending messages

If one of these assumptions is dropped, the circularity problem is easily solved: if announcements do not need to be true, then all states are consistent; if announcements are only propositional formulas, consistency of a state (w, σ, c) can be trivially checked by evaluating all propositional formulas in σ in the world w. The last point is only a little 359 bit less obvious: if agents cannot imagine pending annoucements, then the definition of the pre-accessibility relation R_a for agent *a* (see Definition 3.3) is that $(w, \sigma, c)R_a(w', \sigma', c')$ 360 if $w \to_a w'$, c(a) = c'(a) and $\sigma|_{c(a)} = \sigma'$: the only sequence of announcements that she 361 considers possible is the one she has already received. In that case, the length of the 362 sequence of announcements $|\sigma|$ together with the size of the formula to evaluate can be 363 used to define truth conditions for consistency and for formulas by induction. Indeed, 364 evaluating a formula $K_a \varphi$ in a state (w, σ, c) only requires evaluating the consistency of 365 states (w', σ', c') such that $|\sigma'| \leq |\sigma|$, which in turn only requires evaluating formulas $\psi \in \sigma$ 366 in states (w', σ'', c') , where σ'' is a strict prefix of σ . 367

We also note that it is possible to solve the circularity problem by only constraining the last assumption instead of completely dropping it. Indeed, under a bounded *non-Zeno behaviour* assumption (only a bounded finite number of discrete events occur in a finite time), and assuming a global clock that is common knowledge, the imagination of the agents is sufficiently constrained to solve the circularity problem rather easily (see Appendix B).

In relation with the above discussion, we point out that the circularity problem does *not* depend on the following assumptions:

- 376 Announcements are broadcast
- 377 Announcements are made by an external source
- 378 Announcements are received in FIFO order.

In Section 4, we will describe several restricted settings in which we manage to overcome this problem. But first, we present a small example to better understand the intuitions behind our logic.

382 3.5. *Example*

We consider two agents $Ag = \{B, C\}$, where *B* stands for Bonnie and *C* for Clyde. Bonnie and Clyde go to rob a bank, and Bonnie stays in the car, while Clyde goes to the vault. At noon, Bonnie notices that Clyde left the paper with the secret code to open the vault in the car. She uses her smartphone to broadcast the code on their chat group. But Clyde has also realized that he forgot the paper, and before he receives Bonnie's message, he sends a message saying that he does not know the code.

In the following, let *p* represent the fact that the secret code is 0000, and *q* the fact that the vault is open. The situation at noon is represented by the following initial pointed Kripke model (\mathcal{M}, w) :

In the initial world w, Bonnie knows p, i.e., she knows the code, but Clyde does not. On the other hand, Clyde knows that q is not true, i.e., he knows that the vault is closed, but Bonnie does not (Clyde could have memorized the code before leaving the car, and thus 397 The initial state at noon is $\binom{w B}{C} = \int_{0}^{\infty} \int_{0}^{\infty}$

Bonnie, and then $\neg K_C p$ is announced by Clyde. The actual state becomes $C : \square \square \square$ Intuitively, since only true announcements are made, we see that $\neg K_C p$ can only be announced before Clyde receives the announcement of p. We would like to verify whether, after Bonnie receives both announcements but Clyde receives neither (the signal inside

$$w \stackrel{B:}{\underset{C}{\otimes}} \stackrel{p \neg K_C p}{\bigotimes}$$

the bank is weak), that is in state $\overline{C} : \{ \boxtimes \boxtimes , Bonnie knows \neg q, i.e., does she know that the vault is not open, and what does she know about Clyde's knowledge. In fact, we can prove that the following holds:$

$$(w,\epsilon,\mathbf{0}) \models \langle p \rangle \langle \neg K_C p \rangle \bigcirc_B \bigcirc_B (K_B \neg q \land \neg K_B K_C p \land \neg K_B \neg K_C p)$$
(4)

- The meaning is that, after both announcements have been made and received by Bonnie but not by Clyde,
- Bonnie knows that the vault is not open: intuitively, because Clyde told her he did not
 have the code, and thus could not have opened it (recall that q represents the situation
- 409 at noon, i.e., before Bonnie announced *p*). In state $\begin{bmatrix} p & \neg K_C p \\ \vdots & \boxtimes \\ C & \vdots & \boxtimes \\ \hline m & \boxtimes \\ m & \boxtimes \\ \hline m & \boxtimes \\ m & \boxtimes \\ \hline m & \boxtimes \\ m$
- 414 Bonnie does not know whether Clyde knows the code (because she does not know
 415 whether Clyde received her message).
- 416 In state $w_{C}^{B} : \bigotimes_{i \in \mathbb{N}}^{p \to K_{C}p}$, Bonnie considers state $w_{C}^{B} : \bigotimes_{i \in \mathbb{N}}^{p \to K_{C}p}$ as possible, and in this state 417 Clyde knows *p*. But Bonnie also considers possible state $w_{C}^{B} : \bigotimes_{i \in \mathbb{N}}^{p \to K_{C}p}$, in which Clyde
- 417 Clyde knows *p*. But Bonnie also considers possible state $V_{C} \in \mathbb{R}^{w}$, in which Clyde 418 considers state $V_{C}^{B} = \int_{\mathbb{R}^{w}} \int_{\mathbb$

We note that this example highlights the differences between asynchronous broadcast 419 420 logic and (synchronous) PAL. Since sending and receiving occur at the same time in 421 PAL, we can informally translate the asynchronous broadcast formula $\langle p \rangle \langle \neg K_C p \rangle \bigcirc_B$ 422 $\neg K_B \neg K_C p$). Assuming the same initial Kripke model and state w, we first notice that 423 in PAL any formula of the form $\langle p \rangle_{PAL} \langle \neg K_C p \rangle_{PAL} \varphi$ is false because after a proposition 424 p is announced, $K_C p$ holds in any circumstances, so that $\neg K_C p$ cannot be announced. 425 We can try to simulate the state, where Bonnie has received both announcements but 426

427 Clyde received neither by using private announcements, made to Bonnie but not to
428 Clyde. Consider the trivial translation of our ABL formula into a formula with private
429 announcements:

$$\langle p \rangle_B \langle \neg K_C p \rangle_B (K_B \neg q \land \neg K_B K_C p \land \neg K_B \neg K_C p)$$

where $\langle \varphi \rangle_B$ means that φ is sent to B and not to C. In all versions of PAL with any 430 variant of synchronous private or semi-private announcement (e.g. Baltag and Moss 431 2004; Baltag et al. 1998; Gerbrandy and Groeneveld 1997; ?), this formula is still false in 432 (\mathcal{M}, w) : because Bonnie receives $\neg K_{CP}$ immediately when it is sent, Clyde cannot receive 433 p between the announcement of $\neg K_C p$ and its reception by Bonnie, so that Bonnie knows 434 that Clyde does not know p. Thus, this example shows that there is no obvious translation 435 from asynchronous broadcast logic to a variant of DEL, and that asynchronous broadcast 436 logic is indeed quite different from DEL. 437

The proof of (4) can be found in Appendix A. Note that here, we anticipate the fact that we are in one of the cases, where we can solve the circularity problem: indeed, all announcements are in the existential fragment of our language (see Section 4.2).

441 **4. Solving the circularity problem**

In this section, we show how we solve the circularity problem identified in the last sectionfor several restricted cases.

444 4.1. When the initial model is a finite tree

445 If we assume in the initial model $\mathcal{M} = (W, \{\rightarrow_a\}_{a \in Ag}, \Pi)$ the relation $\bigcup_a \rightarrow_a$ forms a *finite* 446 *tree* over W, then the circularity problem can be avoided. In this case, we can define a 447 well-founded order on tuples of the form (w, σ, c, φ) , where φ is either a formula in ABL 448 or \checkmark , the idea being that a tuple (w, σ, c, φ) means ' $w, \sigma, c \models \varphi$ '.

- 449 **Definition 4.1.** The order \prec is defined as follows:
- 450 $(w, \sigma, c, \varphi) \prec (w', \sigma', c', \varphi')$ if either
- 452 (1) w is a descendent of w' in \mathcal{M} ,
- 453 2 or w = w' and $|\sigma| + |\phi| < |\sigma'| + |\phi'|$,
- 454 3 or w = w', $|\sigma| + |\phi| = |\sigma'| + |\phi'|$ and c < c',
- 455 where |v| = 1.

456 It is clear that \prec is a well-founded order, and with this order Figure 3 forms a 457 well-founded inductive definition of consistency and semantics of our language.

458 We detail the non-trivial cases. For the second clause of Figure 3, observe that by 459 Point 3 of Definition 4.1, if c' < c then $(w, \sigma, c', \checkmark) < (w, \sigma, c, \checkmark)$, and for all w, σ', c and 460 ψ , by Point 2 of Definition 4.1, we have $(w, \sigma', c, \psi) < (w, \sigma'::\psi, c, \checkmark)$.

- 461 For the clause for $K_a \varphi$ of Figure 3, by Point 1 of Definition 4.1 we have that for all 462 $\varphi, \sigma, \sigma', c, c'$, if w' is a child of w then $(w', \sigma', c', \varphi) \prec (w, \sigma_2 c, K_i \varphi)$.
- Finally, for the clause for $\langle \psi \rangle \varphi$ of Figure 3, by Point 2 of Definition 4.1 we have that $(w, \sigma :: \psi, c, \varphi) \prec (w, \sigma, c, \langle \psi \rangle \varphi)$ for all w, σ, c, φ and ψ (note that $|\langle \psi \rangle \varphi| = 1 + |\psi| + |\varphi|$).

465

Example 4.1. Suppose that we have only one agent *a*. Let us consider initial model \mathcal{M} :

In this model, p holds in the actual world w, but agent a does not know it. Assume 466 that p can be announced at least once $(p \in A)$. We show that, as expected, after p is 467 announced and agent a receives this announcement, agent a knows that p holds. Formally, 468 we prove that, in $\mathcal{M} \otimes \mathcal{A}$, we have $(w, \epsilon, \mathbf{0}) \models \langle p \rangle \bigcirc_a K_a p$. To do so, we in fact show 469 that $(w, [p], a \mapsto 1) \models K_a p$, from which it follows that $(w, [p], 0) \models \bigcirc_a K_a p$, hence the 470 471 desired result. By Definition 3.3 for pre-accessibility relations, every state S such that $(w, [p], a \mapsto 1)R_aS$ is of the form $S = (w', p::\sigma, a \mapsto 1)$, where $w' \in \{u, v\}$ and σ is a 472 sequence of announcements. We must show that every such state either is inconsistent or 473 474 satisfies *p*.

First, for w' = u. According to the clause for p in Figure 3, we have that $(u, \epsilon, \mathbf{0}) \not\models p$, and by the second clause in Figure 3 it follows that $(u, [p], \mathbf{0}) \not\models \checkmark$, from which it also follows also that $(u, [p], a \mapsto 1) \not\models \checkmark$ and $(u, p::\sigma, a \mapsto 1) \not\models \checkmark$, for any σ .

478 Now, for w' = v, by the first clause for p in Figure 3, it follows that for all states of 479 the form $S = (v, p::\sigma, a \mapsto 1)$, $S \models p$, so that finally every state related to $(w, [p], a \mapsto 1)$ is 480 either inconsistent or verifies p. Note that we could also prove that S is consistent.

In practice, this setting can be used as an approximation scheme: taking the tree 481 unfolding of models and cutting them at level ℓ amounts to assuming that agents cannot 482 483 reason about deeper nesting of knowledge. This approach is similar to the well known idea of bounded rationality (Jones 1999), where it is assumed that due to computational 484 limits, agents have only approximate, bounded information about other agents' knowledge, 485 which is represented by allowing only finite-length paths in the Kripke model. We point 486 out, however, that this method of approximation is only appropriate in certain settings. 487 One issue is that it does not allow the accurate representation of transitive accessibility 488 relations, where the leaves of an initial model of any depth ℓ may be reached just by 489 evaluating a formula with one knowledge operator. This setting calls for more work to 490 clarify what the finite tree restriction really captures. 491

492 4.2. Announcing existential formulas

Now, we again allow the initial model to be arbitrary. In particular, we may use one of
the common models of knowledge, for example an initial model whose underlying frame
is KD45 (relations are serial, transitive and Euclidean) or S5 (relations are equivalence
relations); see Fagin *et al.* (2004). However, we restrict the announcement protocol to the
existential fragment of our logic, generated by the following rule:

$$\varphi ::= p \mid \neg p \mid (\varphi \land \varphi) \mid (\varphi \lor \varphi) \mid \hat{K}_a \varphi \mid \bigcirc_a \varphi \mid \langle \varphi \rangle \varphi$$

where p ranges over \mathcal{AP} and a ranges over Ag. Formulas of the existential fragment are called *existential formulas*. If an announcement protocol contains only existential formulas,

$$\begin{split} f(\Gamma) &= \Gamma \cup \left\{ (w,\sigma,c,p) \mid \ p \in \Pi(w) \right\} \\ &\cup \left\{ (w,\sigma,c,\neg p) \mid \ p \notin \Pi(w) \right\} \\ &\cup \left\{ (w,\sigma,c,(\varphi \land \psi)) \mid \ (w,\sigma,c,\varphi) \in \Gamma \ \text{and} \ (w,\sigma,c,\psi) \in \Gamma \right\} \\ &\cup \left\{ (w,\sigma,c,(\varphi \lor \psi)) \mid \ ((w,\sigma,c,\varphi) \in \Gamma \ \text{or} \ (w,\sigma,c,\psi) \in \Gamma \right\} \\ &\cup \left\{ (w,\sigma,c,\hat{K}_a\varphi) \mid \ \text{there exists} \ (w',\sigma',c') \ \text{s.t.} \ (w,\sigma,c)R_a(w',\sigma',c'), \right\} \\ &\cup \left\{ (w,\epsilon,\mathbf{0},\boldsymbol{\checkmark}) \mid \ w \in W \right\} \\ &\cup \left\{ (w,\sigma,c,\boldsymbol{\checkmark}) \mid \ \text{there is} \ c' < c \ \text{s.t.} \ (w,\sigma,c',\boldsymbol{\checkmark}) \in \Gamma \right\} \\ &\cup \left\{ (w,\sigma,c,\boldsymbol{\checkmark}) \mid \ \text{there is} \ c' < c \ \text{s.t.} \ (w,\sigma,c,\psi) \in \Gamma \right\} \\ &\cup \left\{ (w,\sigma,c,\boldsymbol{\checkmark}) \mid \ \text{there is} \ c' < c \ \text{s.t.} \ (w,\sigma,c',\boldsymbol{\checkmark}) \in \Gamma \right\} \\ &\cup \left\{ (w,\sigma,c,\boldsymbol{\checkmark}) \mid \ \text{there is} \ c' < c \ \text{s.t.} \ (w,\sigma,c',\boldsymbol{\checkmark}) \in \Gamma \right\} \\ &\cup \left\{ (w,\sigma,c,\boldsymbol{\checkmark}) \mid \ (w;\sigma',c,\boldsymbol{\checkmark}) \in \Gamma \ \text{and} \ (w,\sigma',c,\psi) \in \Gamma, \right\} \\ &\cup \left\{ (w,\sigma,c,\boldsymbol{\checkmark}) \mid \ c(i) < |\sigma| \ \text{and} \ (w,\sigma,c,\psi) \in \Gamma \ \text{and} \ (w,\sigma::\psi,c,\varphi) \in \Gamma \right\} \\ &\cup \left\{ (w,\sigma,c,\langle\psi\rangle\varphi) \mid \ \sigma::\psi \in \text{Seq}(\mathcal{A}), (w,\sigma,c,\psi) \in \Gamma \ \text{and} \ (w,\sigma::\psi,c,\varphi) \in \Gamma \ \right\} \end{split}$$

Fig. 4. Function f that applies one step of the truth conditions.

500 we call it an *existential announcement protocol*. For instance, the announcement protocol 501 in Example 3.1 is existential.

Here, we tackle the circularity problem by defining consistency and truth conditions separately. We first define as a fixed point the semantics of existential announcements in \mathcal{A} , together with consistency. In a second step, we define the semantics of the full logic with existential announcements as described in Figure 3, using the fixed point to evaluate consistency.

We fix an initial model $\mathcal{M} = (W, \{\rightarrow_a\}_{a \in Ag}, \Pi)$ and an existential announcement 507 protocol A. Let B be the set of all pairs (S, φ) such that S is a state of $\mathcal{M} \otimes \mathcal{A}$ and φ 508 is either a formula in \mathcal{A} or \checkmark , the symbol for consistency. Observe that $(\mathcal{P}(B),\subseteq)$ forms 509 a complete lattice. We now consider the function $f: \mathcal{P}(B) \to \mathcal{P}(B)$ defined in Figure 4. 510 Function f takes a set Γ of truth pairs (pairs (S, φ) such that $S \models \varphi$), and extends it with 511 the new truth pairs that can be inferred from Γ by applying each of the rules in Figure 3 512 once. For instance, if $(w, \sigma, c) \models \varphi$ and $(w, \sigma, c) \models \psi$, then $(w, \sigma, c) \models (\varphi \land \psi)$. That is, if 513 (w, σ, c, φ) and (w, σ, c, ψ) are in Γ , then $(w, \sigma, c, (\varphi \land \psi))$ is in $f(\Gamma)$, which explains line 3 of 514 Figure 4. Every other line of Figure 4 similarly follows from one of the truth conditions. 515 Now, as we restrict to existential formulas, it is easy to see that f is monotone, that 516 is, if $\Gamma_1 \subseteq \Gamma_2$ then $f(\Gamma_1) \subseteq f(\Gamma_2)$. By the Knaster-Tarski theorem (Tarski 1955), f has a 517

518 least fixed point
$$\Gamma^* := \bigcup_{n \in \mathbb{N}} f^n(\emptyset)$$
.

519 We can now define the truth condition for consistency as: $S \models \checkmark$ if $(S, \checkmark) \in \Gamma^*$, and 520 use Figure 3 to define the semantics of the language with existential announcements.

521 **Remark 4.1.** If announcements of the form $K_a \varphi$ were allowed, we would have to add

$$\left\{ (w, \sigma, c, K_a \varphi) \mid \begin{array}{l} \text{for all } (w', \sigma', c') \text{ such that } (w, \sigma, c) R_a(w', \sigma', c'), \\ \text{either } (w', \sigma', c', \checkmark) \notin \Gamma \quad \text{or } (w', \sigma', c', \varphi) \in \Gamma \end{array} \right\}$$

522

523 to the definition of f in Figure 4. But then, if $(w, \sigma, c)R_a(w', \sigma', c')$ we would have:

525 $-(w,\sigma,c,K_ap) \in f(\emptyset);$

526
$$(w, \sigma, c, K_a p) \notin f(\{(w', \sigma', c', \checkmark), (w', \sigma', c', \neg p)\})$$

527 It would thus no longer hold that $f(\Gamma_1) \subseteq f(\Gamma_2)$ whenever $\Gamma_1 \subseteq \Gamma_2$. As f is clearly not a 528 decreasing function either, we would not be able to apply the Knaster-Tarski theorem.

529 **Remark 4.2.** The Knaster–Tarski theorem is often used to define the denotational 530 semantics of programming languages (Winskel 1993) in the same spirit as what we 531 do here to define consistency.

532 **5. Semantic properties**

In this section, we establish some semantic properties of our logic. First, we compare it with PAL, explaining why ABL is not a conservative extension of PAL when we have at least two agents. Then, we establish some validities of ABL that show how the correctly defined semantics captures the intuitions we have about asynchrony.

537 For the rest of the section, we assume that we have a class of initial models and a 538 class of announcement protocols for which the circularity problem can be solved and 539 the semantics defined as in Figure 3 (for example, arbitrary initial models and positive 540 announcements), and we discuss some validities of our logic.

541 5.1. Difference from PAL

We discuss the difference between the semantics of our logic and those of PAL. In PAL, 542 every time an announcement is made, the Kripke model is updated by removing possible 543 544 worlds where the announcement is not true (see Definition 2.3). This amounts to using the new information to delete epistemic alternatives that are no longer considered possible: 545 546 since announcements are true, a world where an announcement is not true is not a possible world. In our case, epistemic alternatives cannot be deleted at the time of the 547 announcement, since announcements are not received immediately by the agents, and in 548 549 general agents can even have an unbounded number of pending announcements to read. Instead, this pruning is performed directly in the semantics of the knowledge operator, 550 by eliminating all possible states that are not consistent: the pruning is not performed at 551 the moment of the announcement, but is delayed until a knowledge operator is evaluated. 552 Thus, the update operation in PAL and the consistency check in our logic play the 553 same role. This is also reflected in the circularity problem, which stems from a mutual 554 555 dependence between the definition of the semantics and, in the case of PAL, that of the update, and in the case of our logic, that of consistency. 556

557 We also note that if there are at least two agents, our logic is *not* a conservative extension 558 of PAL. An intuitive way of seeing this is that in PAL, an announcement immediately 559 becomes common knowledge, while in our setting asynchrony makes common knowledge 560 unachievable. One may be tempted to define a translation tr from PAL to ABL, where 561 all cases of the inductive definition are trivial, except that of the announcement operator 562 which is

563
$$-tr(\langle \psi \rangle_{PAL} \varphi) := \langle tr(\psi) \rangle \bigcirc_{a_1} \cdots \bigcirc_{a_n} tr(\varphi), \text{ where } Ag = \{a_1, \dots, a_n\}$$

564 In the single-agent case, the translation *tr* yields a conservative extension of PAL, but it 565 is not the case when there are at least two agents. One may think that 'after the *synchronous* 566 public announcement of ψ , ϕ holds' is the same thing as 'after the *asynchronous* broadcast 567 of ψ and its reception by all agents, ϕ holds.' But we show that this is not the case.

In PAL, if p is announced, then p immediately becomes common knowledge, which we recall, means that all agents know p, they all know that they all know p, they all know that they all know that they all know p, and so on. On the other hand, in asynchronous systems common knowledge cannot be reached (Halpern and Moses 1990; Moses and Tuttle 1988), and our logic illustrates this phenomenon. Even finite approximations of common knowledge fail to hold in our logic. For instance, while $[p]_{PAL}K_aK_bp$ is a validity of PAL, its translation $[p] \bigcirc_a \bigcirc_b K_a K_b p$ is not valid.

575 **Proposition 5.1.** There exist \mathcal{M} , an announcement protocol \mathcal{A} and a consistent state 576 $S \in \mathcal{M} \otimes \mathcal{A}$ such that $\mathcal{M} \otimes \mathcal{A}, S \not\models [p] \bigcirc_a \bigcirc_b K_a K_b p$.

577 *Proof.* The idea is the following: after announcing p, and after all agents have received 578 the message p, a does not know whether agent b has received p or not. Therefore, a does 579 not know that b knows p. Let us consider the following initial model \mathcal{M} :

$$a, b \longrightarrow w: p \longrightarrow a, b \longrightarrow u: \neg p \longrightarrow a, b$$

The actual world is w. Since p holds in w, it can be announced. Let $\mathcal{A} = \{\!\{p\}\!\}\!$. We prove that $\mathcal{M} \otimes \mathcal{A}, (w, \epsilon, \mathbf{0}) \not\models [p] \bigcirc_a \bigcirc_b K_a K_b p$. To see this, observe that after p has been announced and received by agent a and agent b (i.e., after evaluation of the first three operators of the formula), we reach state $S = (w, [p], \stackrel{a}{b} \mapsto \stackrel{1}{\to} 1)$. But in $\mathcal{M} \otimes \mathcal{A}$, we have (we only represent a part of $\mathcal{M} \otimes \mathcal{A}$, which is infinite):

$$\begin{array}{c|c} u & a : & p \\ b : & \textcircled{b} & & \\ \hline \end{array} & & & \\ \hline \end{array} & & & \\ w & b : & \fbox{b} & & \\ \hline \end{array} \xrightarrow{p} & b \\ \hline \end{array} & & & \\ b & & \\ \hline \end{array} & & & \\ b & & \\ \hline \end{array} \xrightarrow{p} & b \\ \hline \end{array} \\ b & & \\ b & & \\ \hline \end{array} \\ \begin{array}{c} a & : \\ b & : \\ b & : \\ \hline \end{array} \\ \hline \end{array} \xrightarrow{p} & b \\ \hline \end{array} \\ b & & \\ \hline \end{array}$$

Indeed in state $S = (w, [p], \stackrel{a}{b} \stackrel{\mapsto}{\mapsto} \stackrel{1}{1})$ agent *a* considers it possible that agent *b* did not receive announcement *p*, and thus she considers state $S' = (w, [p], \stackrel{a}{b} \stackrel{\mapsto}{\mapsto} \stackrel{1}{0})$ possible. In *S'*, because *b* received no announcement, and in the initial model we have $w \rightarrow_b u$, agent *b* considers it possible that the actual world is *u* and nothing has been announced, i.e. she considers state $S'' = (u, \epsilon, \mathbf{0})$ possible. Because *p* does not hold in *S''*, we have that $S \not\models K_a K_b p$, which concludes the proof.

591 5.2. Validities

592 We say that a formula φ is *valid* if for every initial model \mathcal{M} and every announcement 593 protocol \mathcal{A} in the classes considered, and for every consistent state $S \in \mathcal{M} \otimes \mathcal{A}$, we have 594 $\mathcal{M} \otimes \mathcal{A}, S \models \varphi$. We write $\models \varphi$ to express that φ is valid. In the following proposition, 595 we establish some validities that provide insights into our framework and show how our 596 definitions correctly capture some natural properties that intuitively should hold in the asynchronous framework we consider. 597

598 **Proposition 5.2.** For every $\varphi \in ABL$ and propositional formula ψ , we have that:

 $1. \models \bigcirc_a \bigcirc_b \varphi \leftrightarrow \bigcirc_b \bigcirc_a \varphi$ 599

600 2.
$$\models \bigcirc_a \top \rightarrow (\bigcirc_a \varphi \leftrightarrow \neg \bigcirc_a \neg \varphi)$$

601

3. $\models \neg \bigcirc_a \top \rightarrow [\psi] \bigcirc_a K_a \psi$ 4. $\models \neg \bigcirc_a \top \rightarrow [\psi] \bigcirc_a K_a (\neg \bigcirc_b \top \rightarrow K_b \psi)$ 602

Proof. We prove the first validity and the other three are left to the reader. 603

Suppose that we have $\mathcal{M} \otimes \mathcal{A}_{a}(w,\sigma,c) \models \bigcirc_{a} \bigcirc_{b} \varphi$. By Figure 3, this means that 604 $c(1) < |\sigma|$ and $\mathcal{M} \otimes \mathcal{A}, (w, \sigma, c^{+a}) \models \bigcirc_b \varphi$, and the latter implies that $c^{+a}(b) < |\sigma|$ and 605 $\mathcal{M} \otimes \mathcal{A}, (w, \sigma, (c^{+a})^{+b}) \models \varphi$. Now, because $(c^{+a})^{+b} = (c^{+b})^{+a}$, we obtain that $\mathcal{M} \otimes$ 606 $\mathcal{A}_{a}(w,\sigma,c^{+b})\models \bigcirc_{a}\varphi$, and therefore $\mathcal{M}\otimes\mathcal{A}_{a}(w,\sigma,c)\models \bigcirc_{b}\bigcirc_{a}\varphi$. The proof for the other 607 direction is symmetric. 608 \square

609 Let us comment on these validities. The first one says that it is possible to permute the 610 order of agents that receive next announcements in their respective queues. The second one says that if an agent has an announcement to read, then reading it is a deterministic 611 612 operation. The third one says that if an agent has no pending announcement and some propositional formula is announced, then after reading his next pending announcement, 613 the agent will know that formula. Intuitively, this is because the truth value of a 614 propositional formula does not change, and the agents know this. The last validity 615 illustrates the fact that in our framework, the behaviour of the public channel is common 616 knowledge. Indeed it says that if, in a situation where agent a has read all the announced 617 messages, a propositional formula ψ is announced and agent a reads it, then agent a 618 619 knows that if agent b has read all the announced messages (and in particular the last one, which is ψ), then agent b also knows ψ . In some sense, it means that initially agent a 620 621 knows that agent b will receive the same messages as herself. In the last two validities, 622 we restrict to propositional formulas in order to avoid Moore's paradox (van Ditmarsch 623 et al. 2007).

We also establish the following proposition, which says that if all the \bigcirc_a operators 624 in a formula φ are under the scope of a knowledge operator, then its truth value is 625 left unchanged by the announcement of any formula ψ . Indeed, the knowledge operator 626 considers all possibilities for the content of the agent's channel, so that the possibility that 627 ψ is in the channel is considered, whether ψ was actually announced or not. 628

In the following, in addition to the assumption that models and announcement protocols 629 are restricted to classes for which the semantics is defined, we consider announcement 630 protocols in which each announcement can be made infinitely many times. We call such 631 632 protocols free protocols.

Proposition 5.3. Let φ be a formula in ABL, in which every \bigcirc_a is under the scope of 633 some K_b , and let \mathcal{A}_{∞} be a free protocol. For every initial model \mathcal{M} and consistent state 634 $S = (w, \sigma, c) \in \mathcal{M} \otimes \mathcal{A}_{\infty}$, for every $\psi \in \mathcal{A}_{\infty}$, we have $\mathcal{M} \otimes \mathcal{A}_{\infty}, S \models \langle \psi \rangle \varphi \leftrightarrow \psi \wedge \varphi$. 635

636 This result follows immediately from the following lemma:

Lemma 5.1. Let φ be a formula in ABL, in which every \bigcirc_a is under the scope of some K_b , and let \mathcal{A}_{∞} be a free protocol. For every initial model \mathcal{M} and for every consistent 639 state $(w, \sigma, c) \in \mathcal{M} \otimes \mathcal{A}_{\infty}$, for every $\psi \in \mathcal{A}_{\infty}$ such that $(w, \sigma :: \psi, c)$ is consistent, we have $\mathcal{M} \otimes \mathcal{A}_{\infty}, (w, \sigma :: \psi, c) \models \varphi$ iff $\mathcal{M} \otimes \mathcal{A}_{\infty}, (w, \sigma, c) \models \varphi$.

641 *Proof.* By induction on φ . The Boolean cases are trivial. 642 Case $\varphi = K_a \varphi'$: Since (w, σ, c) is a state, $c(a) \leq |\sigma|$. It is then easy to check that 643 $\{S \mid (w, \sigma :: \psi, c) R_a S\} = \{S \mid (w, \sigma, c) R_a S\}$, and the result follows.

644 Case $\varphi = \langle \psi' \rangle \varphi'$: If $\psi' \notin A_{\infty}$, the formula φ trivially does not hold in both states. 645 Otherwise, because ψ' has infinite multiplicity in $A_{\infty}, \sigma :: \psi' \in \text{Seq}(A_{\infty})$. We therefore have 646 $(w, \sigma :: \psi, c) \models \langle \psi' \rangle \varphi'$ iff $(w, \sigma :: \psi, c) \models \psi'$ and $(w, \sigma :: \psi :: \psi', c) \models \varphi'$.

647 Assume that $(w, \sigma::\psi, c) \models \langle \psi' \rangle \varphi'$, we prove that $(w, \sigma, c) \models \langle \psi' \rangle \varphi'$. We have that 648 $(w, \sigma::\psi, c) \models \psi'$ (hence $(w, \sigma::\psi::\psi', c)$ is consistent) and $(w, \sigma::\psi::\psi', c) \models \varphi'$. Because 649 ψ' is a subformula of φ , each \bigcirc_a in it is in the scope of some K_b ; we can thus apply 650 the induction hypothesis for $(w, \sigma::\psi, c) \models \psi'$, obtaining that $(w, \sigma, c) \models \psi'$. By induction 651 hypothesis on $(w, \sigma::\psi::\psi', c) \models \varphi'$, we get first that $(w, \sigma::\psi, c) \models \varphi'$, then $(w, \sigma, c) \models \varphi'$ 652 and finally $(w, \sigma::\psi', c) \models \varphi'$ (observe that $(w, \sigma::\psi', c)$ is consistent since $(w, \sigma, c) \models \psi'$). 653 We have proved that $(w, \sigma, c) \models \langle \psi' \rangle \varphi'$.

- The other direction is treated the same way.
- Finally, the case $\varphi = \bigcirc_a \varphi'$ is not possible as \bigcirc_a is not under the scope of any K_b . \Box

656 6. Model checking

657 Here, we address the model checking problem when A is a finite multiset, that is, when 658 the support set of A is finite and the multiplicity of each element is an integer. More 659 precisely, we consider the following decision problem:

- 660 input: an initial pointed model (\mathcal{M}, w) , a *finite* multiset of formulas \mathcal{A} (where 661 multiplicities are written in *unary*), a formula φ_0 ;
- 662 output: yes if $\mathcal{M} \otimes \mathcal{A}, (w, \epsilon, \mathbf{0}) \models \varphi_0$, no otherwise.

663 In practice, model checking is used to check a scenario described by A and φ_0 from a 664 given initial situation (\mathcal{M}, w) .

665 6.1. Propositional announcements

666 In this section, we suppose that formulas in A are propositional. Note that in this case 667 (which is a particular case of existential announcements) the circularity problem does 668 not exist, as consistency of a state (w, σ, c) can be trivially checked by verifying that all 669 *propositional* formulas in σ hold in world w of the initial model, according to the classic 670 semantics of propositional logic.

671 We consider the model checking problem for ABL where inputs $(\mathcal{M}, w, \mathcal{A}, \varphi_0)$ are such 672 that \mathcal{A} only contains propositional formulas. We call this problem the *model checking*

673 problem for propositional protocols.

```
function mc(\mathcal{M}, \mathcal{A}, w, \sigma, c, \varphi)
   match \varphi do
      case p: return p \in V(w);
       case \checkmark: return checkconsistency(\mathcal{M}, \mathcal{A}, w, \sigma, c)
                                                                                                                                                (∗√)
       case \neg \psi: return not mc(\mathcal{M}, \mathcal{A}, w, \sigma, c, \psi);
       case (\psi_1 \land \psi_2): return mc(\mathcal{M}, \mathcal{A}, w, \sigma, c, \psi_1) and mc(\mathcal{M}, \mathcal{A}, w, \sigma, c, \psi_2);
       case K_a \psi:
         for (u, \sigma', c') such that w \to_a u, \sigma' \in Seq(\mathcal{A}) and c' is a cut on \sigma' do
             |\mathbf{if} \ \sigma'[1..c(a)] = \sigma[1..c'(a)] \text{ and } \mathsf{mc}(\mathcal{M}, \mathcal{A}, u, \sigma', c', \checkmark) then
                if not mc(\mathcal{M}, \mathcal{A}, u, \sigma', c', \psi) then
                  I return false
         return true
       case \langle \psi \rangle \chi :
         if \sigma::\psi \in Seq(\mathcal{A}) and mc(\mathcal{M}, \mathcal{A}, w, \sigma, c, \psi) then
            return mc(\mathcal{M}, \mathcal{A}, w, \sigma:: \psi, c, \chi);
          else
         return false;
       case \bigcirc_a \psi: return c(a) < |\sigma| and \mathsf{mc}(\mathcal{M}, \mathcal{A}, w, \sigma, c^{+a}, \psi)
```

Fig. 5. Model checking algorithm.

674 **Theorem 6.1.** The model checking problem for propositional protocols is in PSPACE.

- 675 *Proof.* Figure 5 presents an algorithm that takes a pointed model (\mathcal{M}, w) , a finite 676 multiset \mathcal{A} , a sequence $\sigma \in \text{Seq}(\mathcal{A})$, a cut c on σ and a formula φ as an input. To check 677 the consistency of a state (w, σ, c) , we call checkconsistency $(\mathcal{M}, \mathcal{A}, w, \sigma, c)$, which verifies 678 that every (propositional) formula ψ occurring in σ evaluates to true with the valuation 679 $\Pi(w)$.
- 680 It is easily proven by induction that, for all ψ , the following property $P(\varphi)$ holds:

$$\mathcal{M}, \mathcal{A}, (w, \sigma, c) \models \varphi$$
 iff $\mathsf{mc}(\mathcal{M}, \mathcal{A}, w, \sigma, c, \varphi)$ returns true.

This establishes the correctness of the algorithm. We now analyze its complexity.

First, observe that because \mathcal{A} is finite and each element has finite multiplicity, we have that Seq(\mathcal{A}) only contains sequences of length linear in $|\mathcal{A}|$ (recall that multiplicities are written in unary). It is therefore easy to see that the consistency check (* \checkmark) is done in polynomial time in the size of the input and thus requires a polynomial amount of space. Now, the number of nested calls of mc is bounded by the size of the formula to check, and each call requires a polynomial amount of memory for storing local variables, so that the algorithm runs in polynomial space.

690 691

681

- **Theorem 6.2.** The model-checking problem for propositional protocols is PSPACE -hard.
- 692 *Proof.* See Appendix C.
- 693 6.2. Finite tree initial model

In this section, we restrict the set of inputs $\mathcal{M}, \mathcal{A}, w, \varphi_0$ of the model checking problem to those where the initial pointed models (\mathcal{M}, w) are finite trees rooted in w.

696 **Theorem 6.3.** The model-checking problem when we restrict initial models to finite trees 697 is in PSPACE.

698 *Proof.* We consider the algorithm of Figure 5 again but now the consistency checking 699 $(*\checkmark)$ consists of calling the following procedure:

> function checkconsistency($\mathcal{M}, \mathcal{A}, w, \sigma, c$) if c = 0| return true else | for c' < c do | if $mc(\mathcal{M}, \mathcal{A}, w, \sigma, c', \checkmark)$ then | return true return $mc(\mathcal{M}, \mathcal{A}, w, \sigma', c, \checkmark)$ and $mc(\mathcal{M}, \mathcal{A}, w, \sigma', c, \psi)$ where $\sigma = \sigma' :: \psi$

501 Soundness and completeness are proven by induction on inputs using the order \prec 502 defined in Section 4.1.

Concerning the complexity, the argument given in the proof of Theorem 6.1 no longer holds. In order to bound the number of nested calls of mc, we have to remark that from a call of mc to a sub-call of mc:

- i. either we change the current world w in the initial model for a successor u in the finite tree;
- 708 2. or the quantity $|\sigma| + |\varphi| + \sum_{a \in Ag} c(a)$ is strictly decreasing, where $|\varphi|$ is the length of 709 φ and if $\sigma = [\varphi_1, \dots, \varphi_k]$ then $|\sigma| = \sum_{i=1}^k |\varphi_i|$.

Now, the number of times (1) occurs is bounded by the depth $depth(\mathcal{M}, w)$ of the finite 710 tree \mathcal{M}, w . As each φ is either a subformula of the input formula φ_0 or a subformula of a 711 formula in $\mathcal{A}, |\varphi| \leq |\varphi_0| + |\mathcal{A}|$ where $|\mathcal{A}| := \sum_{\psi \in \mathcal{A}} |\psi|$, and where each single formula ψ is 712 counted as many times as it occurs in the multiset \mathcal{A} . Furthermore, $|\sigma| \leq |\mathcal{A}|$ and $c(a) \leq |\mathcal{A}|$. 713 Thus, the quantity $|\sigma| + |\phi| + \sum_{a \in Ag} c(a)$ is bounded by $(|Ag| + 2)|A| + |\phi_0|$. Therefore, the 714 number of nested calls to mc is bounded by $depth(\mathcal{M}, w) \times ((|Ag| + 2)|\mathcal{A}| + |\varphi_0|)$. So the 715 algorithm requires a polynomial amount of memory in the size of the input (recall that 716 717 the multiplicity of \mathcal{A} is encoded in unary). \square

718 6.3. Existential announcements

700

In this subsection, we design an exponential-time algorithm for the model checkingproblem in the case of existential announcements.

Given an input $\mathcal{M}, \mathcal{A}, w, \varphi_0$, the algorithm first computes the least fixed point Γ^* of the function f defined in Section 4.2. Because the number of possible sequences in Seq(\mathcal{A}) is exponential in $|\mathcal{A}|$, the set B of pairs (S, φ) , where $S \in \mathcal{M} \otimes \mathcal{A}$ and $\varphi \in \mathcal{A} \cup \{\mathbf{v}\}$ is of size exponential in the size of the input, and therefore computing the fixed point requires exponential time in the size of the input. This gives us the semantics of consistency for states of $\mathcal{M} \otimes \mathcal{A}$.

- 727 Then, to evaluate φ_0 , we use the procedure mc of Figure 5, where line $(*\mathbf{v})$, which checks the consistency of a state (w, σ, c) , is replaced by checking whether $(w, \sigma, c, \checkmark) \in \Gamma^*$. 728 The algorithm mc also requires exponential time. To sum up: 729
- **Theorem 6.4.** The model-checking problem for existential announcements is in EXPTIME. 730

7. Satisfiability for propositional announcements 731

- 732 In this section, we address the satisfiability problem when \mathcal{A} is a finite multiset of propositional formulas, that is, when the support set of \mathcal{A} is finite, the multiplicity of 733 each element is an integer and formulas in \mathcal{A} are propositional. More precisely, we say 734 that a formula φ_0 is A-satisfiable if there exists an initial pointed model (\mathcal{M}, w) such that 735 $\mathcal{M} \otimes \mathcal{A}, (w, \epsilon, \mathbf{0}) \models \varphi_0$. We consider the following decision problem: 736
- 737 — input: a *finite* multiset of propositional formulas \mathcal{A} (where multiplicities are written in *unary*), a formula φ_0 ; 738
- 739 — output: yes if φ_0 is \mathcal{A} -satisfiable, no otherwise.

In practice, a typical application of the satisfiability problem would be to check that a 740 class of systems described by a formula φ satisfies a property ψ . To do so, one checks 741 whether $\phi \wedge \neg \psi$ is satisfiable. If it is not, then indeed all ϕ -systems satisfy ψ . If it is 742 743 satisfiable, then the algorithm we present here (like all tableau methods) produces a counter-example, i.e., a model (\mathcal{M}, w) such that $\mathcal{M} \otimes \mathcal{A}, (w, \epsilon, \mathbf{0}) \models \varphi \land \neg \psi$, or in other 744 745 words, a φ -system that does not satisfy ψ .

746 7.1. Tableau method description

- 747 Our tableau method manipulates terms that we call tableau terms, which are of the following kind: 748
- 749 $-(w \sigma c \phi)$: w is a world symbol that represents a world of the model M being constructed, σ is a sequence of formulas in Seq(A), c is a cut for σ and φ is a 750 sub-formula of φ_0 that should be true in $\mathcal{M} \otimes \mathcal{A}, (w, \sigma, c)$. 751
- $(w \rightarrow_a u)$: w and u are two world symbols such that $w \rightarrow_a u$ in the model \mathcal{M} being 752 constructed. 753
- \perp : Denotes an inconsistency. 754
- 755 A tableau rule is represented by a numerator \mathcal{N} above a line and a finite list of denominators $\mathcal{D}_1, \ldots, \mathcal{D}_k$ below this line, separated by vertical bars, representing non-756 757 deterministic choice: $rac{\mathcal{N}}{\mathcal{D}_1 \mid \ldots \mid \mathcal{D}_k}$
- 758
- The numerator and the denominators are finite sets of tableau terms. 759

A tableau for input (\mathcal{A}, φ_0) is a finite tree with a set of tableau terms at each node, 760 whose root is 761

 $\Gamma_0 = \{ (w_0 \ \epsilon \ \mathbf{0} \ \varphi_0) \}.$ 762

763 A rule with numerator \mathcal{N} is *applicable* to a node carrying a set Γ if Γ contains an instance 764 of \mathcal{N} for which the rule has not yet been applied. If no rule is applicable, Γ is said to be 765 *saturated*. We call a node *n* an *end node* if the set of tableau terms Γ it carries is saturated, 766 or if $\bot \in \Gamma$. The tableau is extended the following way:

- 1. Choose a leaf node *n* carrying Γ , where *n* is not an end node, and choose a rule applicable to *n*.
- 2. For each denominator \mathcal{D}_i of the rule, create one successor node for *n* carrying the union of Γ with an appropriate instanciation of \mathcal{D}_i .

A branch in a tableau is a path from the root to an end node. A branch is *closed* if its end node contains \perp , otherwise it is *open*. A tableau is *closed* if all its branches are closed, otherwise it is *open*. A pair (\mathcal{A}, φ_0) is said to be *consistent* if no tableau for (\mathcal{A}, φ_0) is closed.

The tableau rules are described in Figure 6, in which we write $(\sigma, c) \sim_a (\sigma', c')$ for $\sigma|_{c(a)} = \sigma'|_{c'(a)}$.

Remark 7.1. Rule *ch* for choosing valuations is necessary for checking consistency of states in rules $K_a \varphi$ and \checkmark . For this reason, rule *ch* is always applied in priority before rules $K_a \varphi$ and \checkmark . In a node carrying Γ and saturated for rule *ch*, if *w* is a world symbol in Γ , we say that σ is true in *w* if the valuation *v*, defined by v(p) = 1 if $(w \in \mathbf{0} \ p) \in \Gamma$ and v(p) = 0 if $(w \in \mathbf{0} \ \neg p) \in \Gamma$, satisfies every formula in σ (recall that in this section announcements are propositional).

783 7.2. Tableau method soundness and completeness

In this section, we prove that the tableau method is sound and complete. Note that we
will establish that every tableau is finite in the complexity analysis of the tableau method
(see Theorem 7.1).

787 **Proposition 7.1.** If (\mathcal{A}, φ_0) is consistent, then φ_0 is \mathcal{A} -satisfiable.

788 *Proof.* Suppose that (\mathcal{A}, φ_0) is consistent, and consider a tableau t for (\mathcal{A}, φ_0) . By 789 assumption, this tableau is open, which means that it has an open branch. Consider one 790 such open branch, and let Γ be the set of tableau terms carried by its end node. We define 791 the model $\mathcal{M} = (W, \{\rightarrow_a\}_{a \in Ag}, \Pi)$, where

792 — $W = \{ w \mid (w \ \sigma \ c \ \varphi) \in \Gamma \text{ for some } \sigma, c \text{ and } \varphi \},\$

793 $\longrightarrow_a = \{(w, u) \mid (w \rightarrow_a u) \in \Gamma\}$ and

794 — for each $w \in W$, $\Pi(w) = \{p \mid (w \in \mathbf{0} \ p) \in \Gamma\}.$

795 We prove that for all $(w \ \sigma \ c \ \phi) \in \Gamma$, it holds that $\mathcal{M} \otimes \mathcal{A}, (w, \sigma, c) \models \phi$. Because 796 $(w_0 \ \epsilon \ \mathbf{0} \ \phi_0)$ is in $\Gamma_0 \subseteq \Gamma$, it follows that ϕ_0 is \mathcal{A} -satisfiable.

197 If $\varphi = p$, by saturation of rule p we have $(w \in \mathbf{0} \ p) \in \Gamma$, thus $p \in \Pi(w)$ by construction 198 of \mathcal{M} , and $\mathcal{M} \otimes \mathcal{A}, (w, \sigma, c) \models p$.

799 If $\varphi = \neg p$, by saturation of rule $\neg p$ we have $(w \in \mathbf{0} \neg p) \in \Gamma$. We cannot have 800 $(w \in \mathbf{0} p) \in \Gamma$, otherwise the branch would be closed by saturation of rule \bot . Therefore 801 $p \notin \Pi(w)$, and $\mathcal{M} \otimes \mathcal{A}, (w, \sigma, c) \models \neg p$.

$\frac{(w \ \sigma \ c \ \varphi)}{(w \ \epsilon \ 0 \ p) \mid (w \ \epsilon \ 0 \ \neg p)} \ ch \text{for all atomic propositions } p \text{ appearing in } \varphi_0 \text{ and } \mathcal{A}$
$\frac{(w \ \sigma \ c \ (\varphi \land \psi))}{(w \ \sigma \ c \ \varphi) \ (w \ \sigma \ c \ \psi)} \land \qquad \frac{(w \ \sigma \ c \ \neg(\varphi \land \psi))}{(w \ \sigma \ c \ \neg\varphi) \ \ (w \ \sigma \ c \ \neg\psi)} \ \neg \land$
$\frac{(w \ \sigma \ c \ p)}{(w \ \epsilon \ 0 \ p)} \leftarrow p \qquad \frac{(w \ \sigma \ c \ \neg p)}{(w \ \epsilon \ 0 \ \neg p)} \leftarrow \neg p \qquad \frac{(w \ \sigma \ c \ \neg \neg \varphi)}{(w \ \sigma \ c \ \varphi)} \neg \neg$ where $p \in \mathcal{AP}$
$\frac{(w \ \sigma \ c \ \bigcirc_a \varphi)}{(w \ \sigma \ c^{+a} \ \varphi)} \bigcirc_a \text{if } c(a) < \sigma \qquad \qquad \frac{(w \ \sigma \ c \ \bigcirc_a \varphi)}{\bot} \bigcirc_a \text{if } c(a) = \sigma $
$\frac{(w \ \sigma \ c \ \neg \bigcirc_a \varphi)}{(w \ \sigma \ c^{+a} \ \neg \varphi)} \ \neg \bigcirc_a \text{if } c(a) < \sigma $
$\frac{(w \ \sigma \ c \ \langle \psi \rangle \varphi)}{(w \ \sigma \ c \ \psi)(w \ \sigma::\psi \ c \ \varphi)} \ \langle \psi \rangle \text{if } \sigma::\psi \in Seq(\mathcal{A}) \frac{(w \ \sigma \ c \ \langle \psi \rangle \varphi)}{\bot} \ \langle \psi \rangle \text{if } \sigma::\psi \notin Seq(\mathcal{A})$
$\frac{(w \ \sigma \ c \ \neg\langle\psi\rangle\varphi)}{(w \ \sigma \ c \ \neg\psi) \mid (w \ \sigma \ c \ \psi)(w \ \sigma :: \psi \ c \ \neg\varphi)} \ \neg\langle\psi\rangle \text{if } \sigma::\psi \in Seq(\mathcal{A})$
$\frac{(w \ \sigma \ c \ K_a \varphi)(w \to_a u)}{(u \ \sigma' \ c' \ \varphi)} K_a \varphi \text{for all } (\sigma', c') \sim_a (\sigma, c) \text{ and } \sigma' \text{ true in } u \text{ (see Remark 3)}$
$\frac{(w \ \sigma \ c \ \neg K_a \varphi)}{(u \ \sigma'_1 \ c'_1 \ \neg \varphi)(w \to_a u) \ \ \cdots \ \ (u \ \sigma'_n \ c'_n \ \neg \varphi)(w \to_a u)} \ \neg K_a \varphi \text{where} \ (\sigma'_i, c'_i) \sim_a (\sigma, c) $ and $u \text{ is fresh}$
$\frac{(w \ \sigma \ c \ \varphi)}{\bot} \checkmark \text{if } \sigma \text{ is not true in } w \qquad \frac{(w \ \epsilon \ 0 \ p)(w \ \epsilon \ 0 \ \neg p)}{\bot} \bot \text{for } p \in \mathcal{AP}$

Fig. 6. Tableau rules.

For boolean connectives, the result follows by saturation of the appropriate tableau rule, plus application of the induction hypothesis.

804 If $\varphi = \bigcirc_a \varphi'$, we have that $c(a) < |\sigma|$, otherwise Γ would contain \bot by saturation of 805 rule \bigcirc_a and the branch would be closed. Therefore, again by saturation of rule \bigcirc_a , Γ 806 contains ($w \sigma c^{+a} \varphi'$). By induction hypothesis, we get that $\mathcal{M} \otimes \mathcal{A}, (w, \sigma, c^{+a}) \models \varphi'$, and 807 thus $\mathcal{M} \otimes \mathcal{A}, (w, \sigma, c) \models \bigcirc_a \varphi'$.

808 If $\varphi = \neg \bigcirc_a \varphi'$ we apply similar reasoning, except for the case $c(a) = |\sigma|$ in which φ 809 trivially holds.

810	If $\varphi = \langle \psi \rangle \varphi'$, then $\sigma :: \psi \in Seq(\mathcal{A})$, otherwise the branch would be closed. It follows by
811	saturation of rule $\langle \psi \rangle$ that $(w \ \sigma \ c \ \psi)$ and $(w \ \sigma :: \psi \ c \ \phi')$ are in Γ , and we conclude by
812	applying the induction hypothesis.

813 If $\varphi = \neg \langle \psi \rangle \varphi'$, in case $\sigma :: \psi$ is not in Seq(\mathcal{A}), φ trivially holds. Otherwise, by saturation 814 of rule $\neg \langle \psi \rangle$, either ($w \sigma c \neg \psi$) is in Γ , or both ($w \sigma c \psi$) and ($w \sigma :: \psi c \neg \varphi'$) are in 815 Γ . In both cases, we conclude by induction hypothesis.

816 If $\varphi = K_a \varphi'$, let (u, σ', c') be such that $(w, \sigma, c)R_a(u, \sigma', c')$ and $\mathcal{M} \otimes \mathcal{A}, (u, \sigma', c') \models \checkmark$, 817 i.e. σ' is true in u (see Remark 7.1). We have that $w \rightarrow_a u$, so by construction of 818 $\mathcal{M}, (w \rightarrow_a u) \in \Gamma$. Also, since $(w, \sigma, c)R_a(u, \sigma', c')$ we have that $(\sigma, c) \sim_a (\sigma', c')$. By 819 saturation of rule $K_a \varphi$ we thus have that $(u \sigma' c' \varphi') \in \Gamma$, and by induction hypothesis 820 $\mathcal{M} \otimes \mathcal{A}, (u, \sigma', c') \models \varphi'$, which concludes.

821 If $\varphi = \neg K_a \varphi'$, by saturation of rule $\neg K_a \varphi$ there exist $(\sigma', c') \sim_a (\sigma, c)$ and a world symbol 822 *u* such that Γ contains $(u \ \sigma' \ c' \ \neg \varphi)$ and $(w \rightarrow_a u)$. It follows that $(w, \sigma, c) \rightarrow_a (u, \sigma', c')$. 823 We also have that $\mathcal{M} \otimes \mathcal{A}, (u, \sigma', c') \models \checkmark$ (or in other words, σ' is true in *u*), otherwise the 824 branch would be closed by rule \checkmark . Finally, by induction hypothesis, $\mathcal{M} \otimes \mathcal{A}, (u, \sigma', c') \models \neg \varphi'$, 825 and thus $\mathcal{M} \otimes \mathcal{A}, (w, \sigma, c) \models \neg K_a \varphi'$.

- Proposition 7.2. If φ_0 is \mathcal{A} -satisfiable, then (\mathcal{A}, φ_0) is consistent.
- 827 Proof. Suppose that there is a pointed model (\mathcal{M}_0, w_0) such that $\mathcal{M}_0 \otimes \mathcal{A}, (w_0, \epsilon, \mathbf{0}) \models \varphi_0$. 828 We must prove that every tableau for (\mathcal{A}, φ_0) has an open branch.
- We let W_{Γ} denote the set of world symbols appearing in a set of tableau terms Γ . Such a set Γ is said to be *interpretable* if, first, it does not contain \bot and, second, there is an initial model $\mathcal{M} = (W, \{\rightarrow_a\}_{a \in Ag}, \Pi)$ and a mapping $f : W_{\Gamma} \to W$ such that:
- 832 for each $(w \rightarrow_a u) \in \Gamma$, $f(w) \rightarrow_a f(u)$ and
- 833 for each $(w \ \sigma \ c \ \varphi) \in \Gamma$, $\mathcal{M} \otimes \mathcal{A}, (f(w), \sigma, c) \models \checkmark$ and $\mathcal{M} \otimes \mathcal{A}, (f(w), \sigma, c) \models \varphi$.
- 834 We write $\mathcal{M}, f \models \Gamma$ if these two conditions are met.
- Observe that $\Gamma_0 = \{(w_0 \ \epsilon \ \mathbf{0} \ \varphi_0)\}$ does not contain \bot , and by assumption there is a pointed model (\mathcal{M}_0, w_0) such that $\mathcal{M}_0 \otimes \mathcal{A}, (w_0, \epsilon, \mathbf{0}) \models \varphi_0$. So $\mathcal{M}_0, [w_0 \mapsto w_0] \models \Gamma_0$, and Γ_0 is interpretable. We now prove that when a tableau rule is applied in a node that carries an interpretable set of tableau terms and is not an end node, then one of its successors carries an interpretable set. This implies that every tableau for (\mathcal{A}, φ_0) has a branch whose end node carries an interpretable set; in particular, this set does not contain \bot , so the branch is open, which concludes.
- 842 In the following, Γ is the interpretable set of tableau terms in which the rule is applied, 843 and $\mathcal{M} = (W, \{\rightarrow_a\}_{a \in Ag}, \Pi)$ and $f : W_{\Gamma} \to W$ are such that $\mathcal{M}, f \models \Gamma$.
- We do not treat the case of rules for propositional logic as it is straightforward.

845 Rule *ch* for atomic proposition *p*, on numerator $\{(w \ \sigma \ c \ \phi)\}$: If $p \in \Pi(f(w))$, then 846 $\mathcal{M} \otimes \mathcal{A}, (f(w), \epsilon, \mathbf{0}) \models p$, and thus $\mathcal{M}, f \models \Gamma \cup \{(w \ \epsilon \ \mathbf{0} \ p)\}$; otherwise $\mathcal{M}, f \models \Gamma \cup \{(w \ \epsilon \ \mathbf{0} \ -p)\}$. So one of the successors is interpretable.

848 Rule $\bigcirc_a \varphi$ on numerator $\{(w \ \sigma \ c \ \bigcirc_a \varphi)\}$: by assumption, $\mathcal{M} \otimes \mathcal{A}, (f(w), \sigma, c) \models \bigcirc_a \varphi$. 849 Thus, according to the semantics, we necessarily have that $c(a) < |\sigma|$. So the only 850 successor in the tableau carries the set $\Gamma \cup \{(w \ \sigma \ c^{+a} \ \varphi)\}$. Since $(w \ \sigma \ c \ \bigcirc_a \varphi) \in \Gamma$ 851 and $\mathcal{M}, f \models \Gamma, \mathcal{M} \otimes \mathcal{A}, (f(w), \sigma, c) \models \checkmark$, and thus also $\mathcal{M} \otimes \mathcal{A}, (f(w), \sigma, c^{+a}) \models \checkmark$. Besides, because $\mathcal{M} \otimes \mathcal{A}, (f(w), \sigma, c) \models \bigcirc_a \varphi$, we have that $\mathcal{M} \otimes \mathcal{A}, (f(w), \sigma, c^{+a}) \models \varphi$. It follows that $\mathcal{M}, f \models \Gamma \cup \{(w \ \sigma \ c^{+a} \ \varphi)\}$, and the successor is interpretable.

Rule $\neg \bigcirc_a \varphi$ on numerator $\{(w \ \sigma \ c \ \neg \bigcirc_a \varphi)\}$: the application of this rule requires that $c(a) < |\sigma|$ hold. So the fact that $\mathcal{M} \otimes \mathcal{A}, (f(w), \sigma, c) \models \neg \bigcirc_a \varphi$ holds implies $\mathcal{M} \otimes \mathcal{A}, (f(w), \sigma, c^{+a}) \models \neg \varphi$. The consistency aspect is treated like for rule $\bigcirc_a \varphi$, and we obtain that $\mathcal{M}, f \models \Gamma \cup \{(w \ \sigma \ c^{+a} \ \neg \varphi)\}$, hence the successor is interpretable.

Rule $\langle \psi \rangle \varphi$ on numerator $\{(w \ \sigma \ c \ \langle \psi \rangle \varphi)\}$: We have that $\mathcal{M} \otimes \mathcal{A}, (f(w), \sigma, c) \models \langle \psi \rangle \varphi$, so $\sigma :: \psi \in \mathsf{Seq}(\mathcal{A})$, which implies that it is the first version of the rule that is applied. We also have that $\mathcal{M} \otimes \mathcal{A}, (f(w), \sigma, c) \models \psi$ and $\mathcal{M} \otimes \mathcal{A}, (f(w), \sigma :: \psi, c) \models \varphi$. From the former and the fact that $\mathcal{M}, f \models \Gamma \ni (w \ \sigma \ c \ \psi) \varphi$, we obtain that $\mathcal{M} \otimes \mathcal{A}, (f(w), \sigma :: \psi, c) \models \checkmark$. It follows that $\mathcal{M}, f \models \Gamma \cup \{(w \ \sigma \ c \ \psi), (w \ \sigma :: \psi \ c \ \varphi)\}$, and thus the only possible successor is interpretable.

Rule $\neg \langle \psi \rangle \varphi$ on numerator $\{(\psi \sigma c \neg \langle \psi \rangle \varphi)\}$: First, because $\{(\psi \sigma c \neg \langle \psi \rangle \varphi)\} \in$ 864 Γ , we have $\mathcal{M} \otimes \mathcal{A}(f(w), \sigma, c) \models \checkmark$. Also, the application of this rule requires that 865 $\sigma:: \varphi \in Seq(\mathcal{A})$. So the fact that $\mathcal{M} \otimes \mathcal{A}, (f(w), \sigma, c) \models \neg \langle \psi \rangle \varphi$ holds implies that either 866 $\mathcal{M} \otimes \mathcal{A}, (f(w), \sigma, c) \models \neg \psi$ or $\mathcal{M} \otimes \mathcal{A}, (f(w), \sigma :: \psi, c) \models \neg \varphi$. If $\mathcal{M} \otimes \mathcal{A}, (f(w), \sigma, c) \models \neg \psi$, we 867 obtain that $\mathcal{M}, f \models \Gamma \cup \{(w \ \sigma \ c \ \neg \psi)\}$, and the first successor is interpretable. Otherwise 868 we have both $\mathcal{M} \otimes \mathcal{A}, (f(w), \sigma :: \psi, c) \models \neg \varphi$ and $\mathcal{M} \otimes \mathcal{A}, (f(w), \sigma, c) \models \psi$. The latter implies 869 that $\mathcal{M} \otimes \mathcal{A}, (f(w), \sigma :: \psi, c) \models \checkmark$; we obtain that $\mathcal{M}, f \models \Gamma \cup \{(w \ \sigma :: \psi \ c \ \neg \phi)\}$, and the 870 second successor is interpretable. 871

Rule $K_a \varphi$ on numerator $\{(w \ \sigma \ c \ K_a \varphi), (w \rightarrow_a u)\}$, for some $(\sigma', c') \sim_a (\sigma, c)$ and σ' true 872 in u: First, since rule ch has the priority over rule $K_a \varphi$, we know that Γ is saturated for 873 rule ch. Also, since $(w \rightarrow_a u) \in \Gamma$ and tableau terms of this form can only be introduced 874 by rule $\neg K_a \varphi$ together with a tableau term of the form $(u \sigma'' c'' \varphi')$, then there is one 875 such tableau term in Γ . By saturation of rule *ch*, it follows that for each *p* appearing in 876 φ_0 and \mathcal{A} , either $(u \in \mathbf{0} \ p)$ or $(u \in \mathbf{0} \ \neg p)$ is in Γ . This defines a valuation v for u 877 that, by assumption, makes σ' true (see Remark 7.1). Because $\mathcal{M}, f \models \Gamma$, we have that 878 879 $\Pi(f(u))$ agrees with v on all atomic propositions in A. Since by assumption v satisfies all formulas in σ' , so does $\Pi(f(u))$, and therefore $\mathcal{M} \otimes \mathcal{A}, (f(u), \sigma', c') \models \checkmark$. Now, since 880 $\mathcal{M}, f \models \Gamma$ and $(w \rightarrow_a u) \in \Gamma$, we have that $f(w) \rightarrow_a f(u)$, and because $(w \sigma c K_a \varphi) \in \Gamma$, 881 it holds that $\mathcal{M} \otimes \mathcal{A}, (f(w), \sigma, c) \models K_a \varphi$. Since $f(w) \rightarrow_a f(u)$ and $(\sigma, c) \sim_a (\sigma', c')$, we have 882 that $(f(w), \sigma, c)R_a(f(u), \sigma', c')$. As we have seen that $\mathcal{M} \otimes \mathcal{A}, (f(u), \sigma', c') \models \checkmark$, we finally 883 884 have that $\mathcal{M} \otimes \mathcal{A}, (f(u), \sigma', c') \models \varphi$, thus $\mathcal{M}, f \models \Gamma \cup \{(u \ \sigma' \ c' \ \varphi)\}$, and the successor is 885 interpretable.

Rule $\neg K_a \varphi$ on numerator $\{(w \ \sigma \ c \ \neg K_a \varphi)\}$: since $\mathcal{M} \otimes \mathcal{A}, (f(w), \sigma, c) \models \neg K_a \varphi$, there exist $u \in W, \sigma'$ and c' such that $(f(w), \sigma, c)R_a(u, \sigma', c'), \mathcal{M} \otimes \mathcal{A}, (u, \sigma', c') \models \checkmark$ and $\mathcal{M} \otimes \mathcal{A}, (u, \sigma', c') \models \neg \varphi$. Recall that $(f(w), \sigma, c)R_a(u, \sigma', c')$ means that $f(w) \rightarrow_a u$ and $(\sigma, c) \sim_a (\sigma', c')$. Clearly, $\mathcal{M}, f[u \mapsto u] \models \{(u \ \sigma' \ c' \ \neg \varphi)(w \rightarrow_a u)\}$, and because u is fresh, $f[u \mapsto u]$ coincides with f on all world symbols appearing in Γ , so that $\mathcal{M}, f[u \mapsto u] \models \Gamma$. Finally, the denominator corresponding to σ', c' is interpretable (there are only finitely many possible σ' and c', see proof of Theorem 7.1).

893 Rule \checkmark on numerator { $(w \ \sigma \ c)$ }: because Γ is interpretable, this rule cannot 894 be applied. Indeed, assume it is applied. Because rule *ch* is applied in priority, Γ is 895 saturated for rule *ch*. With reasoning similar to that followed for rule $K_a \varphi$, we obtain that the valuation v defined by Γ for w coincides with $\Pi(f(w))$ on all atomic propositions appearing in φ_0 and \mathcal{A} , and thus they agree on all formulas in σ . Yet on the one hand, since $(w \ \sigma \ c \ \varphi) \in \Gamma$ and $\mathcal{M}, f \models \Gamma$, we have that $\mathcal{M} \otimes \mathcal{A}, (f(w), \sigma, c) \models \checkmark$ and thus $\Pi(f(w))$ satisfies all formulas in σ . On the other hand, because the rule \checkmark is applied, vdoes not satisfy all formulas in σ , and we have a contradiction.

901 Rule \perp on numerator $\{(w \ \epsilon \ \mathbf{0} \ p), (w \ \epsilon \ \mathbf{0} \ \neg p)\}$: because $\mathcal{M}, f \models \Gamma$ this cannot 902 happen, as otherwise we would have both $p \in \Pi(f(w))$ and $p \notin \Pi(f(w))$.

Theorem 7.1. The satisfiability problem for finite propositional protocols is in
 NEXPTIME .

905 *Proof.* Let \mathcal{A} be a propositional and finite protocol and φ_0 be the formula to check. The 906 algorithm to check whether φ_0 is \mathcal{A} -satisfiable consists of non-deterministically applying 907 tableau rules of Figure 6 from the initial tableau { $(w \in \mathbf{0} \ \varphi_0)$ }.

Each world symbol w except w_0 is created by rule $\neg K_a$ with a formula φ_w , and the number of times this rule is applied to terms with w as world symbol is linear in φ_w . These world symbols can be ordered in a tree structure (a world symbol created by applying rule $\neg K_a$ in a tableau term with world symbol w is a child of w), and the modal depth of φ_w formulas is strictly decreasing in the tree. So the number of created world symbols w is exponential in the size of φ_0 .

914 In addition, recall that the number of possible sequences of announcements σ is 915 exponential in the size of A, and the number of possible cuts c is $|A|^{|Ag|}$. Therefore, the 916 number of different tableau terms ($w \sigma c \psi$) is exponential in $|\phi_0| + |A|$.

At each step, the algorithm is executing a rule that adds at least one term. As the number of terms is exponential, the number of rule applications is exponential, and thus the running time of the (non-deterministic) algorithm is exponential. So the satisfiability problem when the protocol is finite and propositional is in NEXPTIME.

921 We now establish the matching lower bound.

Theorem 7.2. The satisfiability problem for finite propositional protocols with at least two
 agents is NEXPTIME -hard.

924 Proof. See Appendix D.

925 8. Related work

We review several research areas related to different aspects of the present work.

927 8.1. Existing logics for asynchrony

As far as we know, there has not been much work on the relationship between knowledge, announcements and asynchrony. In (Dégremont *et al.* 2011), asynchrony in DEL is studied, with the notion of asynchrony being that an agent cannot tell whether an event has occurred if her epistemic state is unchanged. This notion of asynchrony is different from the one we consider in this work: indeed in Dégremont *et al.* (2011), different agents can

have a different idea of how many events have occurred so far, because some events might
be completely unnoticed by some agents. So in one setting asynchrony is due to events
being completely unobserved, while in the other (the one considered in this work) it is due
to a delay between the occurrence of an event (the announcement) and its observation
(the reception).

A logic dealing with knowledge and asynchrony is also developed in (Panangaden and Taylor 1992), but in this setting, messages do not have logical content: for example, the logic does not allow for announcements about knowledge or about the effect of other announcements. (Fagin *et al.* 1992) is concerned with knowledge in multi-agent, dynamic systems which may be asynchronous, but does not explicitly model communication, and in particular the effects of asynchronous sending and receiving of true announcements, which is the focus of our work.

Recently, van Ditmarsch developed a logic of asynchronous announcements in (van 945 Ditmarsch 2017). The major difference between our framework and that one is our third 946 basic principle, that agents are able to imagine all possible pending messages. In van 947 Ditmarsch's work, agents in fact do not consider any pending or future announcements 948 possible; they only consider a message possible after they have received it. So in our work, 949 an agent a has three sources of uncertainty: first, uncertainty about the state arising from 950 951 the underlying Kripke model; second 'past uncertainty,' that is, uncertainty about which of the messages that a has received have already been received by other agents; and 952 953 third, 'future uncertainty,' uncertainty about what messages are pending in the channel but unread by a, or which messages may be broadcast in the future. In van Ditmarsch's 954 955 work, agents only have the first two sources of uncertainty: uncertainty arising from the underlying Kripke model, and 'past uncertainty.' This means that agents may not consider 956 the current state possible, and may even have false knowledge. For example, if agents a 957 and b initially do not know true proposition p, and then p is broadcast, in van Ditmarsch's 958 framework, if a has received broadcast p and b has not, b considers it impossible that a959 knows p, even though a does indeed know p. Symbolically, $K_a p \wedge K_b \neg K_a p$. In our logic 960 this is not the case: even when b has not received the broadcast of p, b considers it 961 962 possible that p has been broadcast and received by a, so the formula $K_{ap} \wedge K_b \neg K_a p$ can never hold in our models. In general, $K_a \varphi \rightarrow \varphi$ in our logic, while this is not the case in 963 van Ditmarsch's logic. 964

965 8.2. Semi-private announcements and dynamic epistemic logic

On first glance, asynchronous broadcast logic has some similarities with semi-private 966 announcement logic, (Baltag and Moss 2004; Baltag et al. 1998; Gerbrandy and Groeneveld 967 1997; ?). Logics with semi-private announcements follow the same basic idea as PAL, but 968 rather than announcements being received by the entire group of agents, each message 969 is announced to a subset of agents, while the rest of the agents know the message was 970 971 announced to that group, but do not know what the content of the message was. In the general setting, group A receives message m and updates their knowledge accordingly, 972 973 while the agents not in group A know that A received either m or its negation, $\neg m$, and update their knowledge accordingly. The identity of the group receiving each message is 974

975 common knowledge for everyone. On the surface, this logic has some similarities with asynchronous broadcast logic: at any time, a certain group of agents has received each 976 message, while others have not. However, like other variants of PAL, logics of semi-977 private announcements are synchronous: a message is sent and received simultaneously, 978 and thus common knowledge is achieved immediately by the group of agents receiving 979 the message. Furthermore, even the group of agents who do not receive the message 980 have synchronous information, since they immediately know that the other agents have 981 982 received some message. Overall, in this setting, the agents have less uncertainty about 983 one another's knowledge than in the asynchronous setting. In fact, the issues of semi-984 private messages and asynchrony are orthogonal; one could imagine an asynchronous logic of semi-private announcements, where each member of group A eventually receives 985 986 announcement m, and the rest of the agents eventually receive the information that group A has been asynchronously sent either m or $\neg m$. 987

988 8.3. Arbitrary public announcement logic

Arbitrary public announcement logic (APAL) (Balbiani et al. 2007) has some similarities 989 to our approach. In this logic, one can ask whether some formula holds after any 990 possible announcement; this is not possible in our logic, but because agents can imagine 991 pending messages, our knowledge operator considers any possible future sequence of 992 announcements that follows the protocol, which is a related idea. Interestingly, the 993 satisfiability problem for APAL is undecidable, but decidability can be achieved by 994 considering a constraint similar to our restriction to existential announcements (French 995 996 and van Ditmarsch 2008; van Ditmarsch et al. submitted).

997 8.4. Distributed systems

- The systems we consider are closely related to the notion of *total order broadcast* in distributed systems (Raynal 2013, p. 154):
- 1000 1. if a message is received, then it means that it has been broadcast;
- 1001 2. no message is received twice;
- 1002 3. if an agent received φ before φ' , they all receive φ before φ' ;
- 1003 4. φ causally precedes φ' implies that no agent receives φ' before φ ;
- 1004 5. if a message is broadcast, all agents will eventually receive it.

1005 The first point holds in our system since a message (a formula) is only received if it is in the queue, which is the list of broadcast messages. The second point holds because a 1006 1007 message is received when an agent's cut is increased to include that message from the queue, which only occurs once for each message. The third point holds because we have 1008 FIFO channels, and thus agents all receive messages in the same order, the order in which 1009 they are announced. The fourth point follows from the fact that in our systems we only 1010 consider a state $(w, \sigma :: \psi, c)$ consistent if $(w, \sigma, c) \models \psi$, and because messages are received 1011 in order. The fifth point is not directly modelled in our systems since we only consider 1012 1013 finite histories, but it is a kind of liveness constraint that we will probably be led to consider when we extend the logic with temporal operators (see next section). 1014

1015 More recently, (Griesmayer and Lomuscio 2013) studies the model checking of dis-1016 tributed systems with respect to epistemic specifications. Although this work is in a 1017 synchronous setting, it is quite close to our approach in spirit, and shows that epistemic 1018 issues in distributed systems have practical implications, and a logical approach to these 1019 concerns can be fruitful.

Finally, we note that our definition of asynchronous models $\mathcal{M} \otimes \mathcal{A}$, especially the notion of cuts, is in the spirit of Lamport (1978).

1022 **9. Future work**

This work is a first attempt to develop an epistemic logic for reasoning about asynchronous 1023 announcements. In the future, we would like to overcome the circularity problem, and 1024 define the semantics for the most general case (removing the finite tree and existential 1025 conditions). Using coinduction to define the set of consistent states may be one approach 1026 to this problem. Once we have defined the semantics for the general case, if possible, 1027 we hope to provide a complete axiomatization and a general model-checking algorithm. 1028 1029 We also plan to implement the model-checking algorithms. Actually, we believe that the 1030 model checking of our logic could be reduced to recently proposed succinct languages 1031 for DEL (Charrier and Schwarzentruber 2015, 2017). Therefore, we could use symbolic techniques as presented in (van Benthem et al. 2015). 1032

Second, we would like to model more general situations of asynchronous communica-1033 tion. We plan to consider the case where messages are not read in FIFO order, but are 1034 received and read in arbitrary order. We also plan to model the origin of the messages, 1035 allowing formulas such as 'After agent a broadcasts φ , ψ holds.' In our current setting, 1036 when the external broadcaster makes a new announcement, the only effect is to queue it 1037 in the channel without affecting anyone's epistemic state. However, in the case where the 1038 agents themselves make the announcements, agent a making an announcement should 1039 1040 impact her knowledge: after the announcement she should know, for instance, that the channel is not empty. She should also know that after another agent checks their channel, 1041 that agent will know that ψ has been announced. 1042

Third, it would be interesting to add temporal operators to our language, in order to express properties like 'After p is announced and agent a receives it, *eventually* she will know that agent b knows p' (assuming that agents are forced to read announcements eventually).

Finally, we would like to model not only asynchronous broadcasts on a public channel but also private asynchronous communications between agents in the system. In essence, this amounts to defining a complete asynchronous version of DEL (van Ditmarsch *et al.* 2007).

1051

We would like to thank Hans van Ditmarsch who hosted the three authors in Nancy and
who was the initiator of studying asynchrony in DEL. We acknowledge support from
ERC project EPS 313360.

1150 Appendix A.

1151 Here, we prove that, in the example of Section 3.5, we indeed have that

$$(w,\epsilon,\mathbf{0})\models \langle p\rangle\langle \neg K_C p\rangle \bigcirc_B \bigcirc_B (K_B \neg q \land \neg K_B K_C p \land \neg K_B \neg K_C p)$$

1152 1.
$$(w, \epsilon, \mathbf{0}) \models \langle p \rangle \langle \neg K_C p \rangle \bigcirc_B \bigcirc_B (K_B \neg q \land \neg K_B K_C p \land \neg K_B \neg K_C p)$$
 iff $(w, \epsilon, \mathbf{0}) \models p$, which
1153 is clearly true, and $(w, p, \mathbf{0}) \models \langle \neg K_C p \rangle \bigcirc_B \bigcirc_B (K_B \neg q \land \neg K_B K_C p \land \neg K_B \neg K_C p)$.

1154 2.
$$(w, p, \mathbf{0}) \models \langle \neg K_C p \rangle \bigcirc_B \bigcirc_B (K_B \neg q \land \neg K_B K_C p \land \neg K_B \neg K_C p)$$
 iff $(w, p, \mathbf{0}) \models \neg K_C p$ and
($w, p :: \neg K_C p, \mathbf{0}) \models \bigcirc_B \bigcirc_B (K_B \neg q \land \neg K_B K_C p \land \neg K_B \neg K_C p)$.

1156 (a)
$$(w, p, \mathbf{0}) \models \neg K_C p$$
 iff $(w, p, \mathbf{0}) \not\models K_C p$.

1157 (b) $(w, p, 0) \not\models K_C p$ iff there exists S' s.t. $(w, p, 0)R_C S'$, $S' \models \checkmark$ and $S' \not\models p$. We notice 1158 that $(v, \epsilon, 0)$ meets the requirements for S', so we conclude that $(w, p, 0) \models \neg K_C p$.

1159 3.
$$(w, p :: \neg K_C p, \mathbf{0}) \models \bigcirc_B \bigcirc_B (K_B \neg q \land \neg K_B K_C p \land \neg K_B \neg K_C p)$$
 iff $(w, p :: \neg K_C p, \overset{B \rightarrow 1}{C \mapsto 0}) \models \bigcirc_B (K_B \neg q \land \neg K_B K_C p \land \neg K_B \neg K_C p)$.

1161 4.
$$(w, p :: \neg K_C p, \stackrel{B \mapsto 1}{_{C \mapsto 0}}) \models \bigcirc_B (K_B \neg q \land \neg K_B K_C p \land \neg K_B \neg K_C p)$$
 iff $(w, p :: \neg K_C p, \stackrel{B \mapsto 2}{_{C \mapsto 0}}) \models$
1162 $(K_B \neg q \land \neg K_B K_C p \land \neg K_B \neg K_C p).$

1163 5.
$$(w, p :: \neg K_C p, \overset{B \mapsto 2}{C \mapsto 0}) \models (K_B \neg q \land \neg K_B K_C p \land \neg K_B \neg K_C p)$$
 iff $(w, p :: \neg K_C p, \overset{B \mapsto 2}{C \mapsto 0}) \models K_B \neg q$
1164 and $(w, p :: \neg K_C p, \overset{B \mapsto 2}{C \mapsto 0}) \models \neg K_B K_C p$ and $(w, p :: \neg K_C p, \overset{B \mapsto 2}{C \mapsto 0}) \models \neg K_B \neg K_C p$.

1169 7.
$$(w, p :: \neg K_C p, \overset{B \mapsto 2}{_{C \mapsto 0}}) \models \neg K_B K_C p$$
 iff $(w, p :: \neg K_C p, \overset{B \mapsto 2}{_{C \mapsto 0}}) \not\models K_B K_C p$.

1170 (a) $(w, p :: \neg K_C p, \stackrel{B \to 2}{_{C \to 0}}) \not\models K_B K_C p$ iff $\exists S'$ s.t. $(w, p :: \neg K_C p, \stackrel{B \to 2}{_{C \to 0}}) R_B S'$ and $S' \models \checkmark$ and 1171 $S' \not\models K_C p$.

1172 (b)
$$S' \not\models K_C p$$
 iff $\exists S''$ s.t. $S'R_C S''$ and $S'' \not\models \checkmark$ and $S'' \not\models p$. We can choose $S' = (w, p :: \neg K_C p, \overset{B \mapsto 2}{C \mapsto 0})$ and $S'' = u, \epsilon, \mathbf{0}$ and we have that $(w, p :: \neg K_C p, \overset{B \mapsto 2}{C \mapsto 0})R_B S', S' \models \checkmark,$
1174 $S'R_C S'', S'' \models \checkmark$ and $S'' \not\models p$.

1175 8.
$$(w, p :: \neg K_C p, \stackrel{B \mapsto 2}{_{C \mapsto 0}}) \models \neg K_B \neg K_C p$$
 iff $(w, p :: \neg K_C p, \stackrel{B \mapsto 2}{_{C \mapsto 0}}) \not\models K_B \neg K_C p$.

1176 9.
$$(w, p :: \neg K_C p, \overset{B \mapsto 2}{C \mapsto 0}) \not\models K_B \neg K_C p$$
 iff $\exists S'$ s.t. $(w, p :: \neg K_C p, \overset{B \mapsto 2}{C \mapsto 0}) R_B S'$ and $S' \models \checkmark$ and
1177 $S' \not\models \neg K_C p$, i.e. $S' \models K_C p$.

1178 10. Thus,
$$(w, p :: \neg K_C p, \stackrel{B \mapsto 2}{C \mapsto 0}) \not\models K_B \neg K_C p$$
 iff $\exists S'$ s.t. $(w, p :: \neg K_C p, \stackrel{B \mapsto 2}{C \mapsto 0}) R_B S'$ and $\forall S''$ if
1179 $S' R_C S''$ and $S'' \models \checkmark$, then $S'' \models p$. We can choose $S' = (w, p :: \neg K_C p, \stackrel{B \mapsto 2}{C \mapsto 1})$ and
1180 then we see that for any consistent S'' , if $S' R S''$ then $S'' \models p$. This shows that
1181 $(w, p :: \neg K_C p, \stackrel{B \mapsto 2}{C \mapsto 0}) \models \neg K_B \neg K_C p$.

1182 Appendix B.

1183 We consider the notion of (non-)Zeno behaviours, from the field of timed and hybrid 1184 systems. We describe how, modulo the adoption of a form of asynchrony weaker than the one considered in this work, this notion of non-Zeno behaviour could allow us to solve
the circularity problem for the semantics of the full language, for arbitrary announcements
and initial models.

In timed and hybrid systems, a behaviour of a system is a *Zeno behaviour* if countably infinitely many discrete events occur in a finite time (Corradini *et al.* 2003; Zhang *et al.* 2001). This is of course impossible in real systems, but such behaviours can occur in models of systems due to abstraction, and many works either study how to detect such behaviours, eliminate them, or directly consider only non-Zeno models, i.e., models that do not present Zeno behaviours.

1194 Similarly, let us here assume that our systems are non-Zeno: only a finite number of discrete events (announcements/reception of formulas) occur in a finite time interval. In 1195 1196 fact, we make the stronger assumption that the number of messages sent during one unit of time is bounded. Without loss of generality, we suppose that the number of 1197 messages sent during one unit of time is at most one (otherwise, change the time unit). 1198 We also suppose that reading a formula takes one unit of time. These assumptions are 1199 somewhat idealistic, since the time necessary to send or read a message may be influenced 1200 by many factors, such as the length of the message. However, it may be achievable in 1201 some circumstances, for example by waiting after sending or receiving a message, in order 1202 to use a uniform amount of time. 1203

Note that in the rest of the paper, we never mentioned *time* in our systems. Here, we need to for the notion of non-Zeno systems to make sense. We thus assume a global clock, and in addition, we make the rather strong assumption that all agents have access to this clock, and that this is common knowledge.

1208 Fagin *et al.* (1992, p. 333) wrote:

1209 Is the system synchronous? That is, is there a 'global clock' that every process can 'see,' so that 1210 every process 'knows the time'?

With the assumption that agents have access to a global clock, our systems are not 1211 asynchronous according to this definition. However, we argue that this definition does 1212 not apply here, and that even with the global clock assumption our framework remains 1213 asynchronous in spirit. The first reason is that communication remains asynchronous: the 1214 delay between sending of an announcement and reception by each agent is unbounded. 1215 1216 The second reason is that even though agents have access to a global clock and thus know the time, they cannot talk about it and synchronize. However, knowing the time 1217 1218 and the fact that at most one announcement is made per time unit allows agents to 1219 refine their pre-accessibility relation by removing all possible states that contain too many announcements. This is enough to solve the problem of circular definition, as we detail 1220 1221 now.

First, we introduce the time of the global clock in the states of the models, so that formulas are now evaluated on states of the form (w, σ, c, t) , where (w, σ, c) is as before and t is the time represented as a positive integer. Note that because we assumed that sending of an announcement takes one time unit, we always have that $|\sigma| \leq t$. 1227

We define the satisfaction relation $(w, \sigma, c, t) \models \varphi$ by induction as follows:

$(w, \sigma, c, t) \models p$	if	$p \in \Pi(w)$
$(w,\sigma,c,t)\models(\varphi_1\wedge\varphi_2)$	if	$(w, \sigma, c, t) \models \varphi_1$ and $(w, \sigma, c, t) \models \varphi_2$
$(w, \sigma, c, t) \models \neg \varphi$	if	$(w,\sigma,c,t) \not\models \varphi$
$(w,\sigma,c,t)\models K_a\varphi$	if	for all S' s.t. $(w, \sigma, c)R_a(w', \sigma', c'), \sigma' \leq t$
		and $(w', \sigma', c', t) \models \checkmark, (w', \sigma', c', t) \models \varphi$
$(w, \sigma, c, t) \models \langle \psi \rangle \varphi$	if	$\sigma:: \psi \in \text{Seq}(\mathcal{A}), (w, \sigma, c, t) \models \psi \text{ and } (w, \sigma:: \psi, c, t+1) \models \varphi$
$(w,\sigma,c,t)\models\bigcirc_a\varphi$	if	$c(a) < \sigma $ and $(w, \sigma, c^{+a}, t+1) \models \varphi$
		where $c^{+a}(b) = \begin{cases} c(b) & \text{if } b \neq a \\ c(b) + 1 & \text{if } b = a \end{cases}$
$(w, \epsilon, 0, t) \models \checkmark$		
$(w, \sigma, c, t) \models \checkmark$	if	either there is $c' < c$ such that $(w, \sigma, c', t) \models \checkmark$
		or $\sigma = \sigma' :: \psi$ and there is $t' < t$ such that
		$(w,\sigma',c)\in\mathcal{S},\ (w,\sigma',c,t')\models\checkmark$
		and $(w, \sigma', c, t') \models \psi$

The definition is by induction on the lexicographical order on $(t, |\varphi|)$. Observe that in the last clause, where $(w, \epsilon, \mathbf{0}, t) \models \checkmark$ requires $(w, \sigma', c, t') \models \psi$ to be defined, we have t' < t. Also, in the clause for the knowledge operator, we restrict the pre-accessibility relation to those states that do not contain more messages than what can have been announced since the beginning. These two observations suffice to see that the induction is wellfounded.

So in a sense, our strong non-Zeno assumption together with the common knowledge of a global clock tames the effect of the agents' power to imagine pending messages. We already described in Section 3.4, how removing this assumption on agents' power to imagine solves the circularity problem. In this section, we have shown that it is enough to forbid them to imagine too much.

Finally, we show with an example that even with common knowledge of a global clock our framework remains asynchronous.

Example B.1. In synchronous public announcement logic, common knowledge[§] of formula 1241 p is achieved when p is announced. For example, in a two-agent system the following 1242 formula is always true: $\langle p \rangle_{PAI} C_{a,b} p$. In our systems, message sending and reception are 1243 1244 separate, and there is no common knowledge operator, but if systems with common knowledge of a global clock were equivalent to synchronous systems, we would expect 1245 $\langle p \rangle \bigcirc_a \bigcirc_b (K_a K_b p \land K_b K_a p)$ to hold always, since $C_{a,b} p \to K_a K_b p \land K_b K_a p$. However, 1246 it is easy to see that this does not always hold. Consider for instance a system with 1247 two states, u and v, where p holds at u and not at v, and u and v are equivalent for 1248 agents a and b. It is straightforward to see that $(u, \epsilon, \mathbf{0}, 0) \models \neg \langle p \rangle \bigcirc_a \bigcirc_b (K_a K_b p \land K_b K_a p)$. 1249 Furthermore, it can be shown that for any sequence of formulas $\varphi_1, \ldots, \varphi_k$, there exists 1250

[§] In an S5 system, common knowledge of p is the formalization of 'everybody knows p, everybody knows that everybody knows p, and so on.' In particular, $C_{\{a,b\}}p = p \wedge K_a p \wedge K_b p \wedge K_b K_a p \wedge K_b K_a p \wedge ...$

1251 *n* such that $\langle \varphi_1 \rangle \dots \langle \varphi_k \rangle (\bigcirc_a \bigcirc_b)^k (\neg (K_a K_b)^n p \land \neg (K_b K_a)^n p)$, which strongly suggests that 1252 common knowledge is not attainable in these systems.

1253 Appendix C.

1254 **Theorem C.2.** The model checking problem for propositional protocols is PSPACE -hard.

Proof. We give a polynomial-time reduction from the quantified boolean formula (QBF)
satisfiability problem (Sipser 1997) to the model checking problem for propositional
protocols.

1258 *Reduction definition.* Let $\exists p_1 \forall p_2 \dots \forall p_{2n} \chi(p_1, \dots, p_{2n})$ be a quantified boolean formula where 1259 *n* is an integer. We define an instance $(\mathcal{M}, w_0, \mathcal{A}, \varphi_0)$ of the model checking problem for 1260 propositional protocols.

1261 First, we consider fresh atomic propositions p_i^{\top} and p_i^{\perp} for $i \in \{1, ..., 2n\}$, whose intuitive 1262 meanings are respectively ' p_i is true' and ' p_i is false'.

1263 1. We define the model $\mathcal{M} = (W, \{\rightarrow_a\}_{a \in Ag}, \Pi)$ such that:

- 1265 for all $a \in Ag$, $\rightarrow_a = W \times W$;
- 1266 $\Pi(w_{\alpha}) = \{\alpha\}.$
- 1267 2. The world w_0 is $w_{p_1^{\perp}}$ (but it could be any other world in W).

1268 3. The announcement protocol \mathcal{A} is $\{\neg p_1^\top, \dots, \neg p_{2n}^\top, \neg p_1^\perp, \dots, \neg p_{2n}^\perp\}$. 1269 Now, we define the following abbreviations:

-isdef_a(
$$p_i$$
) := ($\hat{K}_a p_i^{\top} \wedge K_a \neg p_i^{\perp}$) \lor ($\hat{K}_a p_i^{\perp} \wedge K_a \neg p_i^{\top}$), to be read ' p_i is defined';

1271 -istrue_a
$$(p_i) := (\hat{K}_a p_i^{\top})$$
, to be read ' p_i is true.

4. The formula φ_0 is ψ_1 , where the sequence $(\psi_\ell)_{\ell:=1,2n+1}$ is defined by induction:

1273 — Base case:
$$\psi_{2n+1} := \chi(\operatorname{istrue}_a(p_1), \dots, \operatorname{istrue}_a(p_{2n}));$$

1274 — Inductive case: for all
$$\ell \in \{1, \dots, 2n\}$$
,

1275
$$- \psi_{\ell} := \hat{K}_a(\bigwedge_{j=1}^{\ell} \mathsf{isdef}_b(p_j) \land \bigwedge_{j=\ell+1}^{2n} \neg \mathsf{isdef}_b(p_j) \land \psi_{\ell+1}) \text{ if } \ell \text{ is odd};$$

1276
$$- \psi_{\ell} := K_b((\bigwedge_{j=1}^{\ell} \mathsf{isdef}_a(p_j) \land \bigwedge_{j=\ell+1}^{2n} \neg \mathsf{isdef}_a(p_j)) \to \psi_{\ell+1}) \text{ if } \ell \text{ is even}$$

1277 We claim that $\exists p_1 \forall p_2 \dots \forall p_{2n} \chi(p_1, \dots, p_{2n})$ is true if, and only if $\mathcal{M} \otimes \mathcal{A}, (w_0, \epsilon, \mathbf{0}) \models \psi_1$.

1278 Reduction correctness We prove by recurrence on ℓ the following property $P(\ell)$, for all 1279 $\ell \in \{1, ..., 2n + 1\}$: For all valuations v, for all $w \in W$ such that $(w, \sigma_{v,\ell}, c_{v,\ell})$ is consistent,

$$v \models_{\mathsf{QBF}} Q_{\ell} p_{\ell} \dots \forall p_{2n} \chi(p_1, \dots, p_{2n}) \text{ iff } \mathcal{M} \otimes \mathcal{A}, (w, \sigma_{v,\ell}, c_{v,\ell}) \models \psi_{\ell}$$

where

$$-Q_{\ell} = \forall \text{ if } \ell \text{ is even and } Q_{\ell} = \exists \text{ if } \ell \text{ is odd};$$

$$-\sigma_{v,\ell} \text{ is any sequence } \sigma \text{ of Seq}(\mathcal{A}) \text{ such that the prefix } \sigma|_{\ell} \text{ is}$$

$$[\neg p_1^{\neg v(p_1)}, \dots, \neg p_{\ell-1}^{\neg v(p_{\ell-1})}];$$

$$-c_{v,1} = \mathbf{0};$$

$$-\text{ if } \ell > 1, c_{v,\ell} = \stackrel{a}{b} \stackrel{\leftrightarrow}{\mapsto} \stackrel{\ell-2}{\ell-1} \text{ if } \ell \text{ is even and } c_{v,\ell} = \stackrel{a}{b} \stackrel{\leftrightarrow}{\mapsto} \stackrel{\ell-1}{\ell-2} \text{ if } \ell \text{ is odd.}$$

The following picture shows a branch of states reached in the asynchronous model $\mathcal{M} \otimes \mathcal{A}$ when we evaluate formula ψ_1 :

1281

1280

where ? stands for either \top or \perp .

1282 P(2n+1) One can check that for all $i, v \models p_i$ iff $w, \sigma_{v,2n+1}, c_{v,2n+1} \models \mathsf{istrue}_a(p_i)$. Using 1283 this, one can prove the base case by induction on χ :

1284
$$v \models_{\text{QBF}} \chi(p_1, \dots, p_{2n}) \text{ iff } w, \sigma_{v,2n+1}, c_{v,2n+1} \models \chi(\text{istrue}_a(p_1), \dots, \text{istrue}_a(p_{2n})).$$

1285 $\frac{P(\ell+1) \Rightarrow P(\ell)}{P(\ell+1)}$ Suppose that $P(\ell+1)$ holds and let us prove that $P(\ell)$ holds. We 1286 consider the case when ℓ is odd (the case when ℓ is even is similar). Let v be a valuation 1287 and w a world such that $(w, \sigma_{v,\ell}, c_{v,\ell})$ is consistent.

1288 $v \models_{\text{QBF}} \exists p_\ell \dots \forall p_{2n} \chi(p_1, \dots, p_{2n})$

1289 iff there exists $v \in \{0, 1\}$ s.t. $v[p_{\ell} := v] \models_{QBF} \forall p_{\ell+1} \dots \forall p_{2n} \chi(p_1, \dots, p_{2n})$

1290 iff there exists $v \in \{0, 1\}$ s.t. for all $u \in W$, if $(u, \sigma_{v[p_{\ell}:=v],\ell+1}, c_{v[p_{\ell}:=v],\ell+1})$ is consistent then $\mathcal{M} \otimes \mathcal{A}, (u, \sigma_{v[p_{\ell}:=v],\ell+1}, c_{v[p_{\ell}:=v],\ell+1}) \models \psi_{\ell+1}$ (by $P(\ell+1)$)

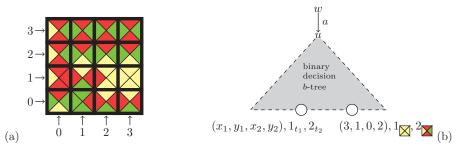

Fig. D1. A 4×4 tiling (k = 4) and an idea of the initial Kripke model.

- 1291 iff there exists $v \in \{0, 1\}$ and a world $u \in W$ s.t. $(u, \sigma_{v[p_{\ell}:=v],\ell+1}, c_{v[p_{\ell}:=v],\ell+1})$ is consistent and $\mathcal{M} \otimes \mathcal{A}, (u, \sigma_{v[p_{\ell}:=v],\ell+1}, c_{v[p_{\ell}:=v],\ell+1}) \models \psi_{\ell+1}$ (because the choice of the world does not matter as long as it satisfies the announcements in $\sigma_{v[p_{\ell}:=v],\ell+1}$, and there always are at least 2n such worlds.)
 - $\inf_{\ell} \mathcal{M} \otimes \mathcal{A}, (w, \sigma_{v, \ell}, c_{v, \ell}) \models \psi_{\ell}$
 - (because $\bigwedge_{j=1}^{\ell} \operatorname{isdef}_{b}(p_{j})$) $\wedge \bigwedge_{j=\ell+1}^{2n} \neg \operatorname{isdef}_{b}(p_{j})$ in ψ_{ℓ} restricts the states that agent a considers possible to those in which agent *b* has received either p_{ℓ}^{\top} or p_{ℓ}^{\perp} .)

1293 Conclusion By
$$P(1)$$
, $\exists p_1 \forall p_2 \dots \forall p_{2n} \chi(p_1, \dots, p_{2n})$ is true iff $\mathcal{M} \otimes \mathcal{A}, w_{p_1^{\perp}}, \epsilon, \mathbf{0} \models \psi_1$.

1294 Appendix D.

1292

Theorem D.2. The satisfiability problem when the protocol is finite and propositional and if the number of agents is greater than 2 is NEXPTIME -hard.

1297 Proof. The proof follows the same idea as the proof of NEXPTIME -hardness of the 1298 satisfiability problem in dynamic epistemic logic (Aucher and Schwarzentruber 2013): 1299 we prove that the satisfiability problem when the protocol is finite and propositional is 1300 NEXPTIME -hard by reducing a NEXPTIME -hard tiling problem (van Emde Boas 1997) 1301 to it. Let C be a countable and infinite set of colors. A *tile type t* is a 4-tuple of colors, 1302 denoted $t = (left(t), right(t), up(t), down(t)) \in C^4$. We consider the following *tiling problem*:

1303Input: a finite set T of tile types, $t_0 \in T$ and a natural number k written in its binary1304form.

1305 **Output:** yes iff there exists a function f from $\{0, ..., k-1\}^2$ to T satisfying:

- 1306 $(t_0) f(0,0) = t_0;$
- 1307 (v) for all $x \in \{0, ..., k-1\}$ and $y \in \{0, ..., k-2\}$: up(f(x, y)) = down(f(x, y+1));
- 1308 (*h*) for all $x \in \{0, ..., k-2\}$ and $y \in \{0, ..., k-1\}$: right(f(x, y)) = left(f(x+1, y)).

1309 In other words, the problem is to decide whether we can tile a $k \times k$ grid with the tile 1310 types of T, t_0 being placed onto (0,0) (Figure D1a shows a 4×4 tiling).

1311 Let us consider an instance (T, t_0, k) of the tiling problem, and without loss of generality, 1312 assume that $k = 2^n$. We define the instance of our satisfiability problem $tr(T, t_0, k) = \langle \mathcal{A}, \varphi \rangle$, 1313 where $\mathcal{A} = \{B_0, \dots, B_{4n-1}, b_0, \dots, b_{4n-1}\}$, where each B_i and b_i is an atomic proposition, and

$$\bigwedge_{j < 4n} (\mathsf{B}_j \land \mathsf{b}_j) \tag{D1}$$

$$\hat{K}_{a} \bigwedge_{\ell < 4n} K_{b}^{\ell} \qquad \left(\bigwedge_{j \ge \ell} (\mathsf{B}_{j} \land \mathsf{b}_{j}) \land \hat{K}_{b} (\mathsf{B}_{\ell} \land \neg \mathsf{b}_{\ell}) \land \hat{K}_{b} (\neg \mathsf{B}_{\ell} \land \mathsf{b}_{\ell}) \land K_{b} ((\mathsf{B}_{\ell} \land \neg \mathsf{b}_{\ell}) \lor (\mathsf{b}_{\ell} \land \neg \mathsf{B}_{\ell})) \land (\mathsf{b}_{i} \rightarrow K_{b} \neg \mathsf{b}_{i}) \land (\mathsf{b}_{i} \rightarrow K_{b} \neg \mathsf{b}_{i}) \land (\neg \mathsf{b}_{i} \rightarrow K_{b} \neg \mathsf{b}_{i})) \right) \qquad (D2)$$

$$K_{a}K_{b}^{4n}\left(\bigvee_{t\in T}\mathbf{1}_{t}\wedge\bigvee_{t\in T}\mathbf{2}_{t}\wedge\bigwedge\left\{\left(\mathbf{1}_{t}\rightarrow\neg\mathbf{1}_{t'}\right)\wedge\left(\mathbf{2}_{t}\rightarrow\neg\mathbf{2}_{t'}\right)\mid t,t'\in T,t\neq t'\right\}\right)$$
(D3)

$$K_a K_b^{4n} \left((x_1 = x_2) \land (y_1 = y_2) \to \bigwedge_{t \in T} (1_t \leftrightarrow 2_t) \right)$$
(D4)

$$K_a(\bigwedge_{i=1}^{2n} K_b^i(K_b\mathsf{B}_i \vee K_b\mathsf{b}_i) \to \bigvee_{t \in T} K_b^{4n}\mathbf{1}_t)$$
(D5)

$$K_a(\bigwedge_{i=2n+1}^{4n} K_b^i(K_b\mathsf{B}_i \vee K_b\mathsf{b}_i) \to \bigvee_{t\in T} K_b^{4n}2_t)$$
(D6)

$$K_a K_b^{4n} \left(((x_1 = 0) \land (y_1 = 0)) \to t_0 \right)$$
 (D7)

$$K_a K_b^{4n} \left((x_1 = x_2) \land (y_2 = y_1 + 1) \to \bigwedge_{t \in T} \left(1_t \to \bigvee_{t' \in T, down(t') = up(t)} 2_{t'} \right) \right)$$
(D8)

$$K_a K_b^{4n} \left((x_2 = x_1 + 1) \land (y_1 = y_2) \to \bigwedge_{t \in T} \left(1_t \to \bigvee_{t' \in T, left(t') = right(t)} 2_{t'} \right) \right)$$
(D9)

Fig. D2. Clauses in φ .

1314 φ is the conjunction of formulas of Figure D2. Observe that this reduction is computable 1315 in polynomial time in the size of (T, t_0, k) . We prove that (T, t_0, k) is a positive instance 1316 of the tiling problem iff φ is \mathcal{A} -satisfiable.

1317 General idea Formula φ enforces an encoding of *two identical* $2^n \times 2^n$ -tilings into a single 1318 tree (see Figure D1b). Each leaf of the tree represents both a position (x_1, y_1) in the first 1319 tiling and a position (x_2, y_2) in the second one. Encoding two copies allows us to compare 1320 a tile with the ones around it locally, in leaves coding for adjacent positions, and thus 1321 without having to compare different leaves of the tree. This greatly simplifies the task of 1322 verifying whether a tree represents a valid tiling.

The tile types of the first tiling are represented by atomic propositions 1_t and the tile types of the second tiling are represented by atomic propositions $2_{t'}$, where t and t' range over T. They hold at a leaf of the tree whose coordinates correspond to (x_1, y_1) and (x_2, y_2) when the tile type of the first tiling at coordinate (x_1, y_1) is t and the tile type of the second tiling at coordinate (x_2, y_2) is t'.

We enforce the consistency of the binary tree: for instance, all $(x_1, y_1, *, *)$ -leaves should be tagged with the same proposition 1_t . To this aim, we need to select all $(x_1, y_1, *, *)$ -

- leaves; this is performed by an 'arbitrary' announcement of coordinates in the first tiling.
 This announcement is imagined by agent *a*, reason why the tree starts in an *a*-child of the
- initial world w (the same technique applies for selecting $(*, *, x_2, y_2)$ -leaves).
- Encoding coordinates. The coordinates (x_1, y_1) and (x_2, y_2) of the two tilings are represented by a valuation over atomic propositions $B_0, \ldots, B_{4n-1}, b_0, \ldots, b_{4n-1}$. More precisely, the set $X_1 = \{B_0, \ldots, B_{n-1}, b_0, \ldots, b_{n-1}\}$ contains the atomic propositions encoding the binary representation of the integer x_1 as follows:
- 1337 B_i means that the *i*th bit of x_1 is 1; b_i means that the *i*th bit of x_1 is 0;
- 1338 if B_i and b_i are both true it means that the *i*th bit is not set yet;
- 1339 valuations where B_i and b_i are both false are never considered.

Similarly, $Y_1 = \{B_n, \dots, B_{2n-1}, b_n, \dots, b_{2n-1}\}$, $X_2 = \{B_{2n}, \dots, B_{3n-1}, b_{2n}, \dots, b_{3n-1}\}$ and $Y_2 = \{B_{3n}, \dots, B_{4n-1}, b_{3n}, \dots, b_{4n-1}\}$ contain the atomic propositions encoding binary representations of integers y_1 , x_2 and y_2 , respectively. For instance, for n = 4, the coordinates $(x_1, y_1) = (4, 3)$ and $(x_2, y_2) = (12, 2)$ are represented at a leaf of the tree by the valuation (we recall that in binary notation, 4 is represented by $\overline{0100}$, 3 is represented by $\overline{0011}$, 12 is represented by $\overline{1100}$ and 2 is represented by $\overline{0010}$):

$$\underbrace{ \begin{array}{c} \neg B_{0}, b_{0} \ , \ \neg b_{1}, B_{1} \ , \ \neg B_{2}, b_{2} \ , \ \neg B_{3}, b_{3} \\ 4 \\ \neg b_{8}, B_{8} \ , \ \neg b_{9}, B_{9} \ , \ \neg B_{10}, b_{10} \ , \ \neg B_{11}, b_{11} \\ 12 \\ \end{array}}_{12} \underbrace{ \begin{array}{c} \neg B_{4}, b_{4} \ , \ \neg B_{5}, b_{5} \ , \ \neg b_{6}, B_{6} \ , \ \neg b_{7}, B_{7} \\ 3 \\ \neg B_{12}, b_{12} \ , \ \neg B_{13}, b_{13} \ , \ \neg b_{14}, B_{14} \ , \ \neg B_{15}, b_{15} \\ 2 \\ \end{array}}_{2}$$

1347

1348 In order to ensure constraints (v) and (h) in the definition of a tiling, we need to 1349 compare tiles that are adjacent in a tiling. Boolean formulas encode the properties $x_1=x_2$, 1350 $x_2=x_1+1$, $y_1=y_2$ or $y_2=y_1+1$. For instance:

1351

$$(x_1 = x_2) \triangleq \bigwedge_{i < n} (\mathsf{B}_i \leftrightarrow \mathsf{B}_{i+2n}) \land (\mathsf{b}_i \leftrightarrow \mathsf{b}_{i+2n})$$
$$(x_2 = x_1 + 1) \triangleq \bigvee_{i < n} \left(\bigwedge_{j < i} (\mathsf{B}_j \leftrightarrow \mathsf{B}_{j+2n}) \land (\mathsf{b}_j \leftrightarrow \mathsf{b}_{j+2n}) \land \mathsf{b}_i \land \mathsf{B}_{i+2n} \land \bigwedge_{i < j < n} (\mathsf{B}_{j+2n} \land \mathsf{b}_j) \right)$$

1352 Announcements with A, we can announce bit values of coordinates in the first or second 1353 tiling and Formula D1 ensures that all formulas in A are true and hence can be successfully 1354 announced.

Tree structure Formula D2 ensures that there exists an *a*-successor *u* such that the epistemic model pointed at *u* is bisimilar up to modal depth 4n to a binary tree (with *b*-relation between nodes) whose leaves' valuations represent all possible pairs of positions $(x_1, y_1, x_2, y_2) \in \{0, ..., 2^n - 1\}^4$. Subformula $\bigwedge_{j>\ell} (\mathsf{B}_j \wedge \mathsf{b}_j)$ means that at level ℓ , the *j*-bits for $j > \ell$ are not set yet. Informally, a leaf corresponds to a pair of one cell in the first tiling and one cell in the second tiling. In Formula D2, modality \hat{K}_a imposes the existence of a new world which is the root of the tree (the root is not the initial world directly because we use agent *a* to imagine possible announcements). This modality \hat{K}_a also considers states in which *b* has received announcements; but as we require the state imagined by agent *a* to be related to states that verify $B_\ell \wedge \neg b_\ell$ and states that verify $\neg B_\ell \wedge b_\ell$ for all ℓ , we rule out the possibility that agent *b* has received any announcement.

Encoding two (unconstrained) tilings Formulas D3 encodes that, at each leaf of the tree, there is exactly one tile type for the first tiling and exactly one tile type for the second tiling. Formula D4 encodes the fact that when these two pairs of coordinates coincide, that is when $x_1=x_2$ and $y_1=y_2$, then the tile type of the first tiling and the tile type of the second tiling are identical.

1371 It may be the case that in the tree, two different leaves with the *same* valuation have 1372 different tile types. Therefore, we also have to constrain the tree so that the leaves denoting 1373 the same position in the first tiling (resp. second tiling) contain the same tile type for the 1374 first tiling (resp. second tiling). This is expressed by formulas D5 and D6.

1375 In Formula D5, modality K_a universally picks a sequence of announcements. The guard 1376 $\bigwedge_{i=1}^{2n} K_b^i(K_b B_i \vee K_b b_i)$ ensures that all bits of (x_1, y_1) have been announced: at each step 1377 $i \leq 2n$ either B_i or b_i has been announced and read by b (checked by the fact that either 1378 b knows B_i or b knows b_i). Maybe more has been announced: for instance B_{2n+1} . In 1379 particular, b considers sequences of announcements where only coordinates (x_1, y_1) have 1380 been announced (and no more). It selects the branches where valuations on the branch 1381 respect the announcement:

1382 — either bits are not yet defined (and then it respects the announcements);

1383 — or a bit of (x_1, y_1) is set and it should respect the announcement.

1384 All leaves in selected branches correspond to the announced value of (x_1, y_1) . Then, the 1385 formula $\bigvee_{t \in T} K_b^{4n} 1_t$ checks that these leaves are of the same tile type *t*. Likewise with 1386 Formula D6 for the second tiling.

- 1387 So, with formulas D3–D6, we encode in the tree two identical (unconstrained) tilings 1388 in a single tree. It remains to enforce that this tiling is valid.
- 1389 Encoding constraints (t_0) , (v) and (h) They are expressed respectively by formulas D7-D9.

1390 As we said at the beginning of the proof, the latter two constraints motivate the encoding

1391 of two tilings. Comparing adjacent positions would not be possible with our epistemic

- language if the tree encoded a single tiling.
- 1393 One can then check that there exists a tiling for the instance (T, t_0, k) of the tiling 1394 problem iff formula φ is A-satisfiable.
