

A functorial excursion
between linear logic and algebraic geometry

Starting point and motivating analogy

In algebraic geometry, there are two kinds of spaces:

- ▷ **schemes** which may be seen as **commutative rings** dualized into **affine schemes** and “glued together” in an appropriate way,
- ▷ **bundles** usually described as **quasi-coherent modules** over the **structure sheaf of rings** a specific scheme X .

Much progress has been made to design **sheaf models** of dependent and homotopy type theory. There, a type is interpreted as a **sheaf** or a **space**.

The position of linear logic is not entirely clear from that point of view. Could we understand linear logic as a **logic of bundles** on spaces?

The category \mathbf{Mod}_R of modules

Every **symm. monoidal closed category** defines a model of linear logic.

Hence: the category \mathbf{Mod}_R of R -modules for a given commutative ring R .

Conjunction as tensor product:

$M \otimes_R N$ as the abelian group $M \otimes N$ quotiented

Implication and hypothetical reasoning as linear hom:

$M \multimap_R N$ as the abelian group of R -module homomorphisms.

Purpose of this talk: extend / adapt this interpretation to **presheaves of modules** over a **covariant presheaf** $X \in [\mathbf{Ring}, \mathbf{Set}]$ of commutative rings.

An axiomatic approach to abelian groups

We want to axiomatize the properties of the category $\mathcal{A} = \mathbf{Ab}$ of abelian groups and homomorphisms between them.

We suppose given a **symmetric monoidal category**

$$(\mathcal{A}, \otimes, 1)$$

where every reflexive pair

$$A \begin{array}{c} \xrightarrow{f} \\ \xrightarrow{g} \end{array} B$$

has a **coequalizer**, preserved by the tensor product on each component.

Reflexive pairs

A **reflexive pair** in a category \mathcal{A} is a pair of maps

$$A \begin{array}{c} \xrightarrow{f} \\ \xrightarrow{g} \end{array} B$$

such that there exists a common **section** of the two maps f and g

$$A \begin{array}{c} \xrightarrow{f} \\ \xleftarrow{s} \\ \xrightarrow{g} \end{array} B$$

in the sense that the equations hold:

$$f \circ s = id_B = g \circ s$$

Rings as commutative monoid objects

A **commutative ring** is an object $R \in \mathcal{A}$ equipped with two maps

$$m : R \otimes R \rightarrow R \qquad e : 1 \rightarrow R$$

making the diagrams commute:

$$\begin{array}{ccc}
 R \otimes R \otimes R & \xrightarrow{m \otimes R} & R \otimes R \\
 \downarrow R \otimes m & & \downarrow m \\
 R \otimes R & \xrightarrow{m} & R
 \end{array}$$

$$\begin{array}{ccc}
 & R \otimes R & \\
 e \otimes R \nearrow & & \searrow m \\
 R & \xrightarrow{id_R} & R \\
 R \otimes e \searrow & & \nearrow m \\
 & R \otimes R &
 \end{array}$$

$$\begin{array}{ccc}
 R \otimes R & \xrightarrow{\gamma_{R,R}} & R \otimes R \\
 \searrow m & & \swarrow m \\
 & R &
 \end{array}$$

The category **Ring** of commutative rings

Given two rings R and S , a **ring homomorphism**

$$u : (R, m_R, e_R) \longrightarrow (S, m_S, e_S)$$

is a map of the category \mathcal{A}

$$u : R \longrightarrow S$$

making the diagrams commute:

$$\begin{array}{ccc} R \otimes R & \xrightarrow{u \otimes u} & S \otimes S \\ m_R \downarrow & & \downarrow m_S \\ R & \xrightarrow{u} & S \end{array}$$

$$\begin{array}{ccc} & 1 & \\ e_R \swarrow & & \searrow e_S \\ R & \xrightarrow{u} & S \end{array}$$

The category **Ring** of commutative rings

The category **Ring** is defined as the category

- ▷ whose objects are the **commutative rings** of the category \mathcal{A} ,
- ▷ whose maps are the **ring homomorphisms** between them.

Note that the category **Ring** has **finite sums** defined by the tensor product.

The sum of two commutative rings R and S is the commutative ring $R \otimes S$ with multiplication map defined using the symmetry:

$$R \otimes S \otimes R \otimes S \xrightarrow{R \otimes \gamma_{R,S} \otimes S} R \otimes R \otimes S \otimes S \xrightarrow{m_R \otimes m_S} R \otimes S$$

and terminal object the monoidal unit 1 seen as a commutative ring.

The category \mathbf{Mod}_R of modules over a ring R

Suppose given a commutative ring R .

An R -**module** is an object $M \in \mathcal{A}$ equipped with a map

$$\text{act} : R \otimes M \longrightarrow M$$

making the diagrams below commute:

$$\begin{array}{ccc} R \otimes R \otimes M & \xrightarrow{m_{R \otimes M}} & R \otimes M \\ R \otimes \text{act} \downarrow & & \downarrow \text{act} \\ R \otimes M & \xrightarrow{\text{act}} & M \end{array}$$

$$\begin{array}{ccc} & R \otimes M & \\ e_{R \otimes M} \nearrow & & \searrow \text{act} \\ M & \xrightarrow{id_M} & M \end{array}$$

Equivalently, an R -module is an **Eilenberg-Moore algebra** for the monad

$$A \mapsto R \otimes A : \mathcal{A} \longrightarrow \mathcal{A}$$

induced by the commutative ring R in the category \mathcal{A} .

The category \mathbf{Mod}_R of modules over a ring R

A **R -module homomorphism** between R -modules

$$f : (M, \text{act}_M) \longrightarrow (N, \text{act}_N)$$

is a map $f : M \rightarrow N$ making the diagram commute:

$$\begin{array}{ccc} R \otimes M & \xrightarrow{R \otimes f} & R \otimes N \\ \text{act}_M \downarrow & & \downarrow \text{act}_N \\ M & \xrightarrow{f} & N \end{array}$$

We write \mathbf{Mod}_R for the category:

- ▷ whose objects are the **R -modules**,
- ▷ whose maps are the **R -module homomorphisms** between them.

The category **Mod** of modules

A **module** is a pair (R, M) consisting of

- ▷ a commutative ring R
- ▷ an R -module (M, act_M)

A **module homomorphism**

$$(u, f) : (R, M) \rightarrow (S, N)$$

is a pair consisting of

- ▷ a ring homomorphism $u : R \rightarrow S$
- ▷ a map $f : M \rightarrow N$ making the diagram commute:

$$\begin{array}{ccc} R \otimes M & \xrightarrow{u \otimes f} & S \otimes N \\ \text{act}_M \downarrow & & \downarrow \text{act}_N \\ M & \xrightarrow{f} & N \end{array}$$

The category **Mod** of modules

The category **Mod** is defined as the category

- ▷ whose objects are the **modules**,
- ▷ whose maps are the **module homomorphisms** between them.

There is an obvious functor

$$\pi : \mathbf{Mod} \longrightarrow \mathbf{Ring}$$

which transports every module (R, M) to its underlying commutative ring R .

For that reason, we find convenient to write

$$u : R \longrightarrow S \quad \vDash \quad f : M \longrightarrow N$$

for a module homomorphism $(u, f) : (R, M) \rightarrow (S, N)$.

The category **Mod** of modules

The notation

$$u : R \longrightarrow S \quad \vDash \quad f : M \longrightarrow N$$

is inspired by the intuition that every ring homomorphism

$$u : R \longrightarrow S$$

induces a **fiber** consisting of all the module homomorphisms of the form

$$(u, f) : (R, M) \longrightarrow (S, N)$$

equivalently, of all the maps $f : M \rightarrow N$ making the diagram commute:

$$\begin{array}{ccc} R \otimes M & \xrightarrow{u \otimes f} & S \otimes N \\ \text{act}_M \downarrow & & \downarrow \text{act}_N \\ M & \xrightarrow{f} & N \end{array}$$

Note that \mathbf{Mod}_R is the fiber of the identity map $id_R : R \rightarrow R$.

The Grothendieck bifibration $\pi : \mathbf{Mod} \rightarrow \mathbf{Ring}$

A well-known fact is that the functor

$$\pi : \mathbf{Mod} \longrightarrow \mathbf{Ring}$$

defines a Grothendieck bifibration.

Every ring homomorphism

$$u : R \longrightarrow S$$

induces a **restriction/extension adjunction** between the fiber categories:

$$\mathbf{Mod}_R \begin{array}{c} \xrightarrow{\mathbf{ext}_u} \\ \perp \\ \xleftarrow{\mathbf{res}_u} \end{array} \mathbf{Mod}_S$$

The restriction of scalar functor

Every S -module (N, act_N) induces a R -module noted

$$\mathbf{res}_u N = (N, \text{act}'_N)$$

with same underlying object N as the original S -module, and with action

$$\text{act}'_N : R \otimes N \rightarrow N$$

defined as the composite:

$$\text{act}'_N = R \otimes N \xrightarrow{u \otimes N} S \otimes N \xrightarrow{\text{act}_N} N$$

The S -module (N, act_N) comes moreover with a module homomorphism

$$u : R \longrightarrow S \quad \vDash \quad \text{id}_N : \mathbf{res}_u N \longrightarrow N \quad (1)$$

which is cartesian in the (original) sense of Grothendieck.

The extension of scalar functor

The restriction of scalar functor

$$\text{res}_u : \mathbf{Mod}_S \longrightarrow \mathbf{Mod}_R$$

has a **left adjoint** noted

$$\text{ext}_u : \mathbf{Mod}_R \longrightarrow \mathbf{Mod}_S$$

One way to construct the functor ext_u is to define the $R \otimes S$ -module

$$R \otimes_u S$$

as the **reflexive coequalizer** of the diagram:

$$R \otimes R \otimes S \begin{array}{c} \xrightarrow{m_R \otimes S} \\ \xleftarrow{R \otimes e_R \otimes S} \\ \xrightarrow{(R \otimes m_S) \circ (R \otimes u \otimes S)} \end{array} R \otimes S$$

The extension of scalar functor

Given three rings R , S_1 and S_2 , we define the **composition functor**

$$\circledast_R : \mathbf{Mod}_{S_1 \otimes R} \times \mathbf{Mod}_{R \otimes S_2} \longrightarrow \mathbf{Mod}_{S_1 \otimes S_2}$$

which transports a pair (M, N) consisting of $\left\{ \begin{array}{l} \text{a } S_1 \otimes R\text{-module } M \\ \text{a } R \otimes S_2\text{-module } N \end{array} \right.$

to the $S_1 \otimes S_2$ -module $M \otimes_R N$ defined as the reflexive coequalizer of

$$M \otimes R \otimes N \begin{array}{c} \xrightarrow{\text{act}_M \otimes N} \\ \xleftarrow{M \otimes e_R \otimes N} \\ \xrightarrow{M \otimes \text{act}_N} \end{array} M \otimes N$$

Here, the two maps $\text{act}_M : M \otimes R \rightarrow M$ and $\text{act}_N : R \otimes N \rightarrow N$ are deduced from the $S_1 \otimes R$ -module structure of M and $R \otimes S_2$ -module structure of N , by restriction of scalar along $R \rightarrow S_1 \otimes R$ and $R \rightarrow R \otimes S_2$.

The extension of scalar functor

The left adjoint functor

$$\mathbf{ext}_u : \mathbf{Mod}_R \longrightarrow \mathbf{Mod}_S$$

is defined as

$$\mathbf{ext}_u : M \mapsto M \circledast_R (R \otimes_u S)$$

by applying the $R \otimes S$ -module

$$R \otimes_u S$$

on the R -module M using the composition functor

$$\circledast_R : \mathbf{Mod}_R \times \mathbf{Mod}_{R \otimes S} \longrightarrow \mathbf{Mod}_S$$

An axiomatic approach to abelian groups (2)

From now on, we make the extra assumption that

the category \mathcal{A} is **symmetric monoidal closed**

and has all coreflexive equalizers.

The internal hom-object in \mathcal{A} is noted **Hom**(M, N).

The category \mathbf{Mod}^\oplus of modules and retromorphisms

A module retromorphism

$$(u, f) : (R, M) \rightarrow (S, N)$$

is a pair consisting of

- ▷ a ring homomorphism $u : R \rightarrow S$
- ▷ a map $f : N \rightarrow M$ making the diagram commute:

$$\begin{array}{ccccc} R \otimes M & \xleftarrow{R \otimes f} & R \otimes N & \xrightarrow{u \otimes N} & S \otimes N \\ \text{act}_M \downarrow & & & & \downarrow \text{act}_N \\ M & \xleftarrow{f} & & & N \end{array}$$

The category \mathbf{Mod}^\ominus of modules and retromorphisms

The category \mathbf{Mod}^\ominus is defined as the category

- ▷ whose objects are the **modules**,
- ▷ whose maps are the **module retromorphisms** between them.

There is an obvious functor

$$\pi^\ominus : \mathbf{Mod}^\ominus \longrightarrow \mathbf{Ring}$$

which transports every module (R, M) to its underlying commutative ring R .

Note that the functor π^\ominus is a Grothendieck fibration, which coincides in fact with the **opposite** of the Grothendieck fibration π .

The Grothendieck bifibration $\pi^\ominus : \mathbf{Mod}^\ominus \rightarrow \mathbf{Ring}$

It turns out that the functor

$$\pi^\ominus : \mathbf{Mod}^\ominus \longrightarrow \mathbf{Ring}$$

defines in fact a Grothendieck bifibration.

The reason is that every ring homomorphism

$$u : R \longrightarrow S$$

induces a **restriction/coextension adjunction** between fiber categories:

$$\mathbf{Mod}_R^\ominus \begin{array}{c} \xrightarrow{\text{coext}_u} \\ \perp \\ \xleftarrow{\text{res}_u} \end{array} \mathbf{Mod}_S^\ominus$$

where the category \mathbf{Mod}_R^\ominus is the opposite of the category \mathbf{Mod}_R .

The coextension of scalar functor

The restriction of scalar functor

$$\mathbf{res}_u : \mathbf{Mod}_S^\oplus \longrightarrow \mathbf{Mod}_R^\oplus$$

has a **left adjoint** noted

$$\mathbf{coext}_u : \mathbf{Mod}_R^\oplus \longrightarrow \mathbf{Mod}_S^\oplus$$

The functor \mathbf{coext}_u transports every R -module (M, \mathbf{act}_M) to the S -module

$$\mathbf{coext}_u(M) = [S, M]_u$$

defined as the coreflexive equalizer of the diagram:

$$\mathbf{Hom}(S, M) \begin{array}{c} \xrightarrow{\mathbf{Hom}(u \otimes S, M) \circ \mathbf{Hom}(m_S, M)} \\ \xleftarrow{\mathbf{Hom}(e_R \otimes S, M)} \\ \xrightarrow{\mathbf{Hom}(R \otimes S, \mathbf{act}_M) \circ \mathbf{Hom}(R \otimes -, R \otimes -)} \end{array} \mathbf{Hom}(R \otimes S, M)$$

The coextension of scalar functor

The coreflexive equalizer $\mathbf{coext}_u(M)$ provides an internal description in the category \mathcal{A} of the set of maps $f : S \rightarrow M$ making the diagram commute:

$$\begin{array}{ccc}
 R \otimes M & \xleftarrow{R \otimes f} & R \otimes S \\
 \downarrow \text{act}_M & & \downarrow u \otimes S \\
 & & S \otimes S \\
 & & \downarrow m_S \\
 M & \xleftarrow{f} & S
 \end{array}$$

or equivalently, as the set of R -module homomorphisms $f : \mathbf{res}_u S \rightarrow M$.

The trifibration $\pi : \mathbf{Mod} \rightarrow \mathbf{Ring}$ of modules

Putting together all the constructions, every ring homomorphism

$$R \xrightarrow{u} S$$

induces three functors

$$\mathbf{Mod}_R \begin{array}{c} \xrightarrow{\mathbf{coext}_u} \\ \xleftarrow{\mathbf{res}_u} \\ \xrightarrow{\mathbf{ext}_u} \end{array} \mathbf{Mod}_S$$

organized into a sequence of adjunctions

$$\mathbf{ext}_u \dashv \mathbf{res}_u \dashv \mathbf{coext}_u$$

where extension of scalar \mathbf{ext}_u is left adjoint, and coextension of scalar \mathbf{coext}_u , right adjoint to restriction of scalar \mathbf{res}_u .

Ringed categories

A **ringed category** is as a pair (\mathcal{C}, π) consisting of

- ▷ a category \mathcal{C} ,
- ▷ a functor $\pi : \mathcal{C} \rightarrow \mathbf{Ring}$ to the category of commutative rings.

Typically, the category **Mod** defines a ringed category, with functor:

$$\pi : \mathbf{Mod} \longrightarrow \mathbf{Ring}$$

The slice 2-category **Cat/Ring** has ringed categories as objects, fibrewise functors and natural transformations as 1-cells and 2-cells.

The 2-category **Cat/Ring** is cartesian, with cartesian product defined by the expected pullback above **Ring**.

Mod as a symmetric monoidal ringed category

The cartesian product of **Mod** with itself is computed by the pullback:

$$\begin{array}{ccc}
 \mathbf{Mod} \times_{\mathbf{Ring}} \mathbf{Mod} & \longrightarrow & \mathbf{Mod} \\
 \downarrow & & \downarrow \pi \\
 \mathbf{Mod} & \xrightarrow{\pi} & \mathbf{Ring}
 \end{array}$$

and comes equipped with a fibrewise tensor product

$$\otimes_{\mathbf{Mod}} : \mathbf{Mod} \times_{\mathbf{Ring}} \mathbf{Mod} \longrightarrow \mathbf{Mod}$$

which transports every pair of modules on the same ring R

$$(R, M) \quad (R, N)$$

to the R -module $(R, M \otimes_R N)$ defined by their tensor product in \mathbf{Mod}_R .

Mod as a symmetric monoidal ringed category

The functor $\otimes_{\mathbf{Mod}}$ transports every pair of module homomorphisms

$$u : R \longrightarrow S \quad \models \quad h_1 : M_1 \longrightarrow N_1$$

$$u : R \longrightarrow S \quad \models \quad h_2 : M_2 \longrightarrow N_2$$

above the same ring homomorphism $u : R \rightarrow S$ to the homomorphism

$$u : R \rightarrow S \quad \models \quad h_1 \otimes_u h_2 : M_1 \otimes_R M_2 \rightarrow N_1 \otimes_S N_2$$

where $h_1 \otimes_u h_2$ is the unique map making the diagram commute:

$$\begin{array}{ccc}
 M_1 \otimes R \otimes M_2 & \xrightarrow{h_1 \otimes u \otimes h_2} & N_1 \otimes S \otimes N_2 \\
 \text{act}_{M_1} \otimes M_2 \downarrow \downarrow M_1 \otimes \text{act}_{M_2} & & \text{act}_{N_1} \otimes N_2 \downarrow \downarrow N_1 \otimes \text{act}_{N_2} \\
 M_1 \otimes M_2 & \xrightarrow{h_1 \otimes h_2} & N_1 \otimes N_2 \\
 \text{quotient map} \downarrow & & \downarrow \text{quotient map} \\
 M_1 \otimes_R M_2 & \xrightarrow{h_1 \otimes_u h_2} & N_1 \otimes_S N_2
 \end{array}$$

Mod as a symmetric monoidal ringed category

In this way, the ring category

$$\pi : \mathbf{Mod} \longrightarrow \mathbf{Ring}$$

defines a **symmetric pseudomonoid** in the 2-category **Cat/Ring**.

This is what we call a **symmetric monoidal ringed category**.

Note that the fibrewise unit of (\mathbf{Mod}, π) is defined as the functor

$$1_{\mathbf{Mod}} : \mathbf{Ring} \longrightarrow \mathbf{Mod}$$

which transports every commutative ring R into itself, seen as an R -module.

Functors of points and Ring-spaces

A **Ring-space** is defined as a covariant presheaf

$$X : \mathbf{Ring} \longrightarrow \mathbf{Set}$$

on the category **Ring** of commutative rings,

To every such **Ring-space** X , we associate its Grothendieck category

$$\mathbf{Points}(X)$$

- ▷ whose objects are the pairs (R, x) with $x \in X(R)$
- ▷ whose maps $u : (R, x) \rightarrow (S, y)$ are ring homomorphisms $u : R \rightarrow S$ transporting the element $x \in X(R)$ to the element $y \in X(S)$, in the sense that

$$X(u)(x) = y.$$

Functors of points and **Ring**-spaces

The category **Points**(X) comes equipped with a **functor of point**

$$\pi_X \quad : \quad \mathbf{Points}(X) \longrightarrow \mathbf{Ring}$$

and thus defines a ringed category.

A map $f : X \rightarrow Y$ of **Ring**-spaces may be equivalently defined as a functor

$$f \quad : \quad \mathbf{Points}(X) \longrightarrow \mathbf{Points}(Y)$$

making the diagram commute:

$$\begin{array}{ccc} \mathbf{Points}(X) & \xrightarrow{f} & \mathbf{Points}(Y) \\ & \searrow \pi_X & \swarrow \pi_Y \\ & \mathbf{Ring} & \end{array}$$

thus defining a functor of ringed categories.

Presheaves of modules

A **presheaf of modules** M on a **Ring-space**

$$X : \mathbf{Ring} \longrightarrow \mathbf{Set}$$

or more simply, **an \mathcal{O}_X -module** M , consists of the following data:

- ▷ for each point $(R, x) \in \mathbf{Points}(X)$, a module $M_x \in \mathbf{Mod}_R$ over the ring R ,
- ▷ for each map $u : (R, x) \rightarrow (S, y)$ in $\mathbf{Points}(X)$, a module homomorphism

$$u : R \longrightarrow S \quad \vDash \quad \theta(u, x) : M_x \longrightarrow N_y$$

living over the ring homomorphism $u : R \rightarrow S$.

Adapted from Demazure-Gabriel (1970) and Kontsevich-Rosenberg (2004).

Presheaves of modules

The map θ is required to satisfy the following functorial properties:

1. first of all, the identity on the point (R, x) in the category **Points**(X) is transported to the identity map on the associated R -module:

$$id_R \quad \vDash \quad \theta(id_{(R,x)}) = id_{M_x}$$

2. then, given two maps

$$(u, x) : (R, x) \rightarrow (S, y) \qquad (v, y) : (S, y) \rightarrow (T, z)$$

in the category **Points**(X), one has:

$$v \circ u \quad \vDash \quad \theta((v, y) \circ (u, x)) = \theta(v, y) \circ \theta(u, x)$$

where composition is computed in the ringed category **Points**(X) \rightarrow **Ring**.

Presheaves of modules

In the sequel, we will use the following equivalent formulation:

Proposition. An \mathcal{O}_X -module M is the same thing as a functor

$$M : \mathbf{Points}(X) \longrightarrow \mathbf{Mod}$$

making the diagram below commute:

$$\begin{array}{ccc} \mathbf{Points}(X) & \xrightarrow{M} & \mathbf{Mod} \\ & \searrow \pi_X & \swarrow \pi \\ & \mathbf{Ring} & \end{array}$$

Note that Kontsevich and Rosenberg (2004) use this specific formulation of presheaves of modules in their work on noncommutative geometry.

The structure presheaf of modules

Every **Ring**-space

$$X : \mathbf{Ring} \longrightarrow \mathbf{Set}$$

comes equipped with a specific presheaf of module, called the **structure presheaf of modules**, and defined as the composite

$$\mathcal{O}_X : \mathbf{Points}(X) \xrightarrow{\pi_X} \mathbf{Ring} \xrightarrow{\mathcal{O}} \mathbf{Mod}$$

where the functor

$$\mathcal{O} = 1_{\mathbf{Mod}} : \mathbf{Ring} \rightarrow \mathbf{Mod}$$

denotes the section of $\pi : \mathbf{Mod} \rightarrow \mathbf{Ring}$ which transports every commutative ring R to itself, seen as an R -module.

The category **PshMod** of presheaves of modules and forward morphisms

A **forward morphism** between presheaves of modules

$$(f, \varphi) : (X, M) \longrightarrow (Y, N)$$

is a morphism (= natural transformation) of **Ring**-spaces $f : X \rightarrow Y$ together with a natural transformation

$$\begin{array}{ccc} \mathbf{Points}(X) & \xrightarrow{\mathbf{Points}(f)} & \mathbf{Points}(Y) \\ & \searrow M & \swarrow N \\ & \mathbf{Mod} & \end{array}$$

$\xrightarrow{\varphi}$

The category **PshMod** of presheaves of modules and forward morphisms

The natural transformation φ is also required to be vertical (or fibrewise) above **Ring**, in the sense that the natural transformation

coincides with the identity natural transformation from π_X to $\pi_Y \circ f$.

The category **PshMod** of presheaves of modules and forward morphisms

There is an obvious functor

$$\mathbf{p} : \mathbf{PshMod} \longrightarrow [\mathbf{Ring}, \mathbf{Set}]$$

which transports every presheaf of modules (X, M) to its underlying **Ring**-space X , and every forward morphism $(f, \varphi) : (X, M) \rightarrow (Y, N)$ to its underlying morphism $f : X \rightarrow Y$ between **Ring**-spaces.

We thus find convenient to write

$$f : X \longrightarrow Y \quad \vDash \quad \varphi : M \longrightarrow N$$

for a forward morphism between presheaves of modules

$$(f, \varphi) : (X, M) \rightarrow (Y, N)$$

The functor \mathbf{p} is a Grothendieck fibration

Every morphism $f : X \rightarrow Y$ of **Ring**-spaces X and Y induces a functor

$$f^* : \mathbf{PshMod}_Y \longrightarrow \mathbf{PshMod}_X$$

which transports every \mathcal{O}_Y -module N into the \mathcal{O}_X -module $N \circ \mathbf{Points}(f)$ obtained by precomposition with the functor $\mathbf{Points}(f)$, as depicted below:

An axiomatic approach to abelian groups (3)

Here, we make the extra assumption that

the category **Ring**

as well as

every category **Mod** _{R} associated to a commutative ring R

has **all small colimits**.

The property holds in the case of the category $\mathcal{A} = \mathbf{Ab}$ of abelian groups.

The functor \mathbf{p} is a Grothendieck bifibration

In that case, it turns out that the functor

$$\mathbf{p} : \mathbf{PshMod} \longrightarrow [\mathbf{Ring}, \mathbf{Set}]$$

is also a Grothendieck bifibration, but for less immediate reasons.

For every morphism $f : X \rightarrow Y$ between **Ring**-spaces, the functor

$$f^* : \mathbf{PshMod}_Y \longrightarrow \mathbf{PshMod}_X$$

has a left adjoint

$$\exists_f : \mathbf{PshMod}_X \longrightarrow \mathbf{PshMod}_Y$$

The functor \mathbf{p} is a Grothendieck bifibration

It is worth noting that the \mathcal{O}_Y -module $\Xi_f(M)$ can be directly described with an explicit formula:

$$\Xi_f(M) : y \in Y(R) \mapsto \bigoplus_{\{x \in X(R), fx=y\}} M_x \in \mathbf{Mod}_R.$$

The adjunction $\Xi_f \dashv f^*$ gives rise to a sequence of natural bijections, which can be formulated in the type-theoretic fashion of PAM-Zeilberger (2015)

$$\frac{id_X : X \rightarrow X \vdash M \rightarrow f^*(N)}{f : X \rightarrow Y \vdash M \rightarrow N} \\ \frac{id_Y : Y \rightarrow Y \vdash \Xi_f(M) \rightarrow N}{f : X \rightarrow Y \vdash M \rightarrow N}$$

The category \mathbf{PshMod}^\oplus of presheaf of modules and backward morphisms

A **backward morphism** between presheaves of modules

$$(f, \psi) : (X, M) \longrightarrow (Y, N)$$

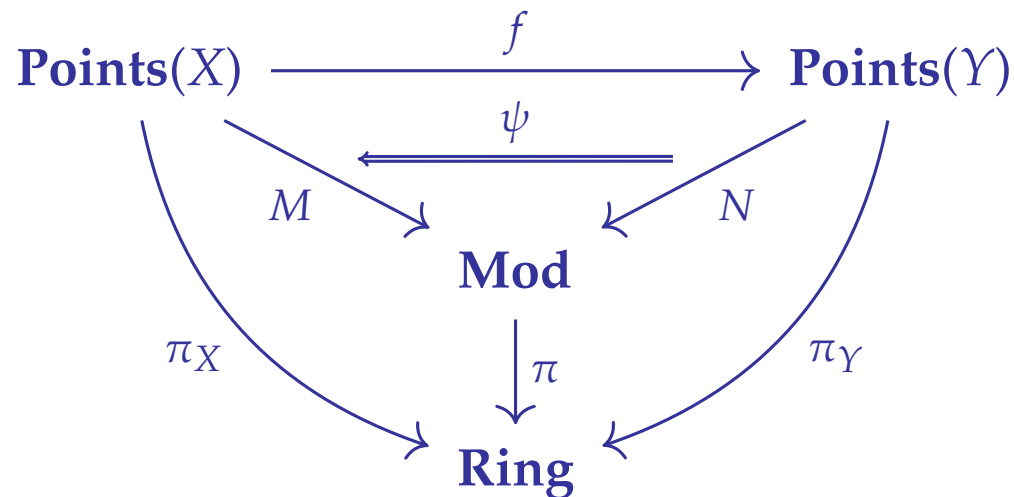

is a morphism (= natural transformation) of **Ring**-spaces $f : X \rightarrow Y$ together with a natural transformation

$$\begin{array}{ccc} \mathbf{Points}(X) & \xrightarrow{f} & \mathbf{Points}(Y) \\ & \searrow M & \swarrow N \\ & \mathbf{Mod} & \end{array}$$

$\xleftarrow{\psi}$

The category \mathbf{PshMod}^\oplus of presheaf of modules and backward morphisms

One requires moreover that ψ is vertical in the sense that the diagram below commutes:

The category \mathbf{PshMod}^\ominus of presheaf of modules and backward morphisms

The category \mathbf{PshMod}^\ominus has presheaves of modules as objects, and backward morphism as morphisms. There is an obvious functor

$$\mathbf{p}^\ominus : \mathbf{PshMod}^\ominus \longrightarrow [\mathbf{Ring}, \mathbf{Set}]$$

We thus find convenient to write

$$f : X \longrightarrow Y \quad \vDash^{op} \quad \psi : M \longrightarrow N$$

for such a backward morphism $(f, \psi) : (X, M) \rightarrow (Y, N)$ between presheaves of modules.

An axiomatic approach to abelian groups (4)

Here, we make the extra assumption that

the category **Ring**

as well as

every category **Mod** _{R} associated to a commutative ring R

has **all small limits**.

The property holds in the case of the category $\mathcal{A} = \mathbf{Ab}$ of abelian groups.

The functor \mathbf{p}^\ominus is a Grothendieck bifibration

As the opposite of the fibration \mathbf{p} , the functor

$$\mathbf{p}^\ominus : \mathbf{PshMod}^\ominus \longrightarrow [\mathbf{Ring}, \mathbf{Set}]$$

is also a Grothendieck fibration with the opposite functor

$$(f^*)^{op} : \mathbf{PshMod}_Y^{op} \longrightarrow \mathbf{PshMod}_X^{op}$$

as pullback functor associated to a morphism $f : X \rightarrow Y$ of **Ring**-spaces.

Fact. There is a **functor**

$$\mathbb{V}_f : \mathbf{PshMod}_X \longrightarrow \mathbf{PshMod}_Y.$$

right adjoint to the functor f^* .

By duality, the functor $(\mathbb{V}_f)^{op}$ is left adjoint to the functor $(f^*)^{op}$.

The functor \mathbf{p} is a Grothendieck trifibration

The adjunction $f^* \dashv \forall_f$ gives rise to a sequence of natural bijections, formulated below in the type-theoretic fashion:

$$\frac{\frac{id_X : X \rightarrow X \Vdash^{op} M \rightarrow f^*(N)}{f : X \rightarrow Y \Vdash^{op} M \rightarrow N}}{id_Y : Y \rightarrow Y \Vdash^{op} \forall_f(M) \rightarrow N}$$

In summary, every morphism $f : X \rightarrow Y$ between **Ring**-spaces X and Y induces three functors

$$\mathbf{PshMod}_X \begin{array}{c} \xrightarrow{\forall_f} \\ \xleftarrow{f^*} \\ \xrightarrow{\exists_f} \end{array} \mathbf{PshMod}_Y$$

organized into a sequence of adjunctions

$$\exists_f \dashv f^* \dashv \forall_f.$$

The category \mathbf{PshMod} is symmetric monoidal closed above the cartesian closed category $[\mathbf{Ring}, \mathbf{Set}]$

The presheaf category $[\mathbf{Ring}, \mathbf{Set}]$ of \mathbf{Ring} -spaces is cartesian closed.

We exhibit a **symmetric monoidal closed structure** on \mathbf{PshMod} designed in such a way that the functor

$$p : \mathbf{PshMod} \longrightarrow [\mathbf{Ring}, \mathbf{Set}]$$

is **symmetric monoidal closed**.

The cartesian structure on $[\mathbf{Ring}, \mathbf{Set}]$

Suppose given a pair of **Ring**-spaces

$$X, Y : \mathbf{Ring} \longrightarrow \mathbf{Set}$$

and a pair of presheaves of modules M and N over them:

$$M \in \mathbf{PshMod}_X \quad N \in \mathbf{PshMod}_Y.$$

The cartesian product $X \times Y$ of **Ring**-spaces is defined pointwise:

$$X \times Y : R \mapsto X(R) \times Y(R).$$

The monoidal structure on \mathbf{PshMod}

The tensor product

$$M \otimes N \in \mathbf{PshMod}_{X \times Y}$$

is defined using the isomorphism:

$$\mathbf{Points}(X \times Y) \cong \mathbf{Points}(X) \times_{\mathbf{Ring}} \mathbf{Points}(Y)$$

as the presheaf of modules

$$\mathbf{Points}(X \times Y) \xrightarrow{(M,N)} \mathbf{Mod} \times_{\mathbf{Ring}} \mathbf{Mod} \xrightarrow{\otimes} \mathbf{Mod}$$

where the functor (M, N) is defined by universality of the pullback.

The monoidal structure on \mathbf{PshMod}

The unit of the tensor product is the structure presheaf of modules

$$(\mathrm{Spec} \mathbb{Z}, \mathcal{O}_{\mathrm{Spec} \mathbb{Z}}) \quad : \quad (R, *_R) \mapsto R \in \mathbf{Mod}_R$$

on the terminal object $\mathrm{Spec} \mathbb{Z}$ of the category $[\mathbf{Ring}, \mathbf{Set}]$.

Here, $*_R$ denotes the unique element of the singleton set $\mathrm{Spec} \mathbb{Z}(R)$.

The closed structure on \mathbf{PshMod}

The internal hom $X \Rightarrow Y$ in $[\mathbf{Ring}, \mathbf{Set}]$ is the covariant presheaf

$$X \Rightarrow Y : \mathbf{Ring} \longrightarrow \mathbf{Set}$$

which associates to every commutative ring R the set

$$X \Rightarrow Y : R \mapsto ([\mathbf{Ring}, \mathbf{Set}]/\mathbf{y}_R)(\mathbf{y}_R \times X, \mathbf{y}_R \times Y)$$

of natural transformations f making the diagram commute:

$$\begin{array}{ccc} \mathbf{y}_R \times X & \xrightarrow{f} & \mathbf{y}_R \times Y \\ & \searrow \pi_{R,X} & \swarrow \pi_{R,Y} \\ & \mathbf{y}_R & \end{array}$$

The closed structure on \mathbf{PshMod}

Here,

$$\mathbf{y}_R \in [\mathbf{Ring}, \mathbf{Set}]$$

denotes the Yoneda presheaf

$$\mathbf{y}_R : S \mapsto \mathbf{Ring}(R, S) : \mathbf{Ring} \longrightarrow \mathbf{Set}$$

generated by the commutative ring R , while

$$\pi_{R,X} : \mathbf{y}_R \times X \longrightarrow \mathbf{y}_R$$

$$\pi_{R,Y} : \mathbf{y}_R \times Y \longrightarrow \mathbf{y}_S$$

denote the first projections in the cartesian category $[\mathbf{Ring}, \mathbf{Set}]$.

The closed structure on \mathbf{PshMod}

The presheaf of modules

$$M \multimap N \in \mathbf{PshMod}_{(X \Rightarrow Y)}$$

is constructed in the following way. To every element

$$f \in (X \Rightarrow Y)(R)$$

we associate the R -module

$$(M \multimap N)_f$$

consisting of all natural transformations φ making the diagram commute:

The closed structure on \mathbf{PshMod}

The closed structure on \mathbf{PshMod}

The R -module

$$(M \multimap N)_f \in \mathbf{Mod}_R$$

associated to the map of **Ring**-space

$$f : \mathbf{y}_R \times X \longrightarrow \mathbf{y}_R \times Y$$

can be computed using the **end formula**

$$(M \multimap N)_f = \int_{(u:R \rightarrow S, x \in X(S)) \in \mathbf{Points}(\mathbf{y}_R \times X)} \mathbf{res}_u ([M_x, N_{f(u,x)}]_S)$$

in the category \mathbf{Mod}_R .

Main result of the talk

Theorem. The tensor product

$$M, N \mapsto M \otimes N$$

and the implication just defined

$$M, N \mapsto M \multimap N$$

equip **PshMod** with the structure of a **symmetric monoidal category**.

This structure is moreover transported by the functor

$$\mathbf{p} : \mathbf{PshMod} \longrightarrow [\mathbf{Ring}, \mathbf{Set}]$$

to the cartesian closed structure of **[Ring, Set]** in the sense that

$$\mathbf{p}(M \otimes N) = X \times Y \qquad \mathbf{p}(M \multimap N) = X \Rightarrow Y$$

for the **Ring**-spaces $X = \mathbf{p}(M)$ and $Y = \mathbf{p}(N)$.

Application: \mathbf{PshMod}_X is a smcc

We establish that the category \mathbf{PshMod}_X associated to a **Ring**-space

$$X : \mathbf{Ring} \longrightarrow \mathbf{Set}$$

is **symmetric monoidal closed**. The tensor product $M \otimes_X N$ of a pair of \mathcal{O}_X -modules M, N is defined as

$$M \otimes_X N := \Delta^*(M \otimes N)$$

where we use the notation

$$\Delta : X \longrightarrow X \times X$$

for the diagonal map induced by the cartesian structure of the presheaf category $[\mathbf{Ring}, \mathbf{Set}]$. The tensorial unit is defined as the structure presheaf of modules \mathcal{O}_X associated to the **Ring**-space X .

Application: \mathbf{PshMod}_X is a smcc

The internal hom $M \dashv\circ_X N$ of a pair of \mathcal{O}_X -modules M, N is defined as

$$M \dashv\circ_X N := \mathit{curry}^*(M \dashv\circ \mathbb{V}_\Delta(N))$$

where

$$\mathit{curry} : X \longrightarrow X \Rightarrow (X \times X)$$

is the map obtained by currying the identity map

$$\mathit{id}_{X \times X} : X \times X \longrightarrow X \times X$$

on the second component X . One obtains that

Proposition. The category \mathbf{PshMod}_X equipped with \otimes_X and $\dashv\circ_X$ defines a symmetric monoidal closed category.

Proof in a nutshell

$$\begin{array}{c}
 \frac{id_X : X \rightarrow X \models (M \otimes_X N) \rightarrow P}{id_X : X \rightarrow X \models \Delta^*(M \otimes N) \rightarrow P} \\
 \frac{id_X : X \rightarrow X \models \Delta^*(M \otimes N) \rightarrow P}{id_X : X \rightarrow X \models^{op} P \rightarrow \Delta^*(M \otimes N)} \\
 \frac{id_X : X \rightarrow X \models^{op} P \rightarrow \Delta^*(M \otimes N)}{\Delta : X \rightarrow X \times X \models^{op} P \rightarrow M \otimes N} \\
 \frac{\Delta : X \rightarrow X \times X \models^{op} P \rightarrow M \otimes N}{id_{X \times X} : X \times X \rightarrow X \times X \models^{op} \forall_\Delta(P) \rightarrow M \otimes N} \\
 \frac{id_{X \times X} : X \times X \rightarrow X \times X \models^{op} \forall_\Delta(P) \rightarrow M \otimes N}{id_{X \times X} : X \times X \rightarrow X \times X \models M \otimes N \rightarrow \forall_\Delta(P)} \\
 \frac{id_{X \times X} : X \times X \rightarrow X \times X \models M \otimes N \rightarrow \forall_\Delta(P)}{curry : X \rightarrow X \Rightarrow (X \times X) \models N \rightarrow M \multimap \forall_\Delta(P)} \\
 \frac{curry : X \rightarrow X \Rightarrow (X \times X) \models N \rightarrow M \multimap \forall_\Delta(P)}{id_X : X \rightarrow X \models N \rightarrow curry^*(M \multimap \forall_\Delta(P))} \\
 \frac{id_X : X \rightarrow X \models N \rightarrow curry^*(M \multimap \forall_\Delta(P))}{id_X : X \rightarrow X \models N \rightarrow (M \multimap_X P)}
 \end{array}$$

Sequence of natural bijections establishing that the functor

$$M \otimes_X - : \mathbf{PshMod}_X \longrightarrow \mathbf{PshMod}_X$$

is left adjoint to the functor

$$M \multimap_X - : \mathbf{PshMod}_X \longrightarrow \mathbf{PshMod}_X$$

for any presheaf of modules $M \in \mathbf{PshMod}_X$.

Application: change-of-basis functors

Moreover, given a morphism $X \rightarrow Y$ in $[\mathbf{Ring}, \mathbf{Set}]$ and two \mathcal{O}_Y -modules M and N , the fact that $\Delta_Y \circ f = (f \times f) \circ \Delta_X$ and the isomorphism

$$(f \times f)^*(M \otimes N) \cong f^*(M) \otimes f^*(N)$$

imply that

$$f^* : \mathbf{PshMod}_Y \longrightarrow \mathbf{PshMod}_X$$

defines a **strongly monoidal functor**, in the sense that there exists a family of isomorphisms

$$m_{X,M,Y,N} : f^*(M) \otimes_X f^*(N) \xrightarrow{\sim} f^*(M \otimes_Y N)$$

$$m_{X,Y} : \mathcal{O}_X \xrightarrow{\sim} f^*(\mathcal{O}_Y)$$

making the expected coherence diagrams commute.

Application: change-of-basis functors

From this follows that

- ▷ the right adjoint functor \mathbb{V}_f is lax symmetric monoidal ;
- ▷ the adjunction $f^* \dashv \mathbb{V}_f$ is lax symmetric monoidal ;
- ▷ the left adjoint functor \mathbb{E}_f is oplax symmetric monoidal ;
- ▷ the adjunction $\mathbb{E}_f \dashv f^*$ is oplax symmetric monoidal.

In particular, the two functors \mathbb{V}_f and \mathbb{E}_f come with families of maps:

$$\begin{array}{l} \mathbb{V}_f(M) \otimes_N \mathbb{V}_f(Y) \longrightarrow \mathbb{V}_f(M \otimes_X N) \qquad \mathcal{O}_Y \longrightarrow \mathbb{V}_f(\mathcal{O}_X) \\ \mathbb{E}_f(M \otimes_X N) \longrightarrow \mathbb{E}_f(M) \otimes_Y \mathbb{E}_f(N) \qquad \mathbb{E}_f(\mathcal{O}_X) \longrightarrow \mathcal{O}_Y \end{array}$$

parametrized by \mathcal{O}_X -modules M and N .

What we did not speak about here

- ▷ the **Sweedler dual construction** of a free commutative coalgebra

- ▷ the induced construction of an **linear-non-linear** adjunction

defining an **exponential modality** $A \mapsto !A$ for linear logic.

Conclusion and future directions

- ▷ work with **sheaves** and **schemes** instead of general presheaves,
- ▷ understand the structure of the inclusion functor

$$\mathbf{qcMod}_X \longrightarrow \mathbf{PshMod}_X$$

from the category \mathbf{qcMod}_X of **quasi-coherent modules**.

- ▷ shift to **derived categories** and clarify the connection

$$\mathbf{linear\ logic} \quad \leftrightarrow \quad \mathbf{Grothendieck-Verdier\ duality}$$

- ▷ explore the connection to **dependent and homotopy type theory**.

Thank you !

The closed structure on PshMod

This condition may be expanded using the notation $f(u, x) = (u, \tilde{f}(u, x))$.

Such a natural transformation φ is a family of module homomorphisms

$$id_S : S \longrightarrow S \quad \vDash \quad \varphi_{u,x} : M_x \longrightarrow N_{\tilde{f}(u,x)}$$

for $u : R \rightarrow S$ and $x \in X(S)$, natural in u and x in the sense that the diagram

$$\begin{array}{ccc} M_x & \xrightarrow{\varphi_{u,x}} & N_{\tilde{f}(u,x)} \\ M_v \downarrow & & \downarrow N_{\tilde{f}(v,v)} \\ M_{x'} & \xrightarrow{\varphi_{v \circ u, x'}} & N_{\tilde{f}(v \circ u, x')} \end{array}$$

commutes for every ring homomorphism $v : S \rightarrow S'$ with $X(v)(x) = x'$.
