#### The material of this talk

- 1.- Planarity on the critical window for random graphs
- 2.- Our result. The strategy
- **3.-** Generating Functions: algebraic methods
- 4.- Cubic planar multigraphs
- 5.- Computing large powers: analytic methods
- 6.— Other applications
- 7.- Further research

### Planarity on the critical window for random graphs

- $\heartsuit$  Independence in the choice of edges.  $\checkmark$
- ♣ The expected number of edges is  $M = \binom{n}{2}p$ . ✓
- $\blacklozenge$  We do not control the number of edges.

There are  $2^{\binom{n}{2}}$  labelled graphs with *n* vertices.

A random graph G(n, M) is the probability space with properties:

- ► Sample space: set of labelled graphs with n vertices and M = M(n) edges.
- Probability: Uniform probability  $\left(\binom{\binom{n}{2}}{M}\right)^{-1}$

Properties:

- $\heartsuit$  Fixed number of edges  $\checkmark$
- ♣ The probability that a fixed edge belongs to the random graph is  $p = \binom{n}{2}^{-1} M$ . ✓

♠ There is not independence.

**EQUIVALENCE**:  $G(n, p) = G(n, M), (n \to \infty)$  for

$$M = \binom{n}{2}p$$

#### The Erdős-Rényi phase transition

Random graphs in G(n, M) present a dichotomy for  $M = \frac{n}{2}$ :

- 1.- (Subcritical)  $M = cn, c < \frac{1}{2}$ : a.a.s. all connected components have size  $O(\log n)$ , and are either trees or unicyclic graphs.
- 2.- (Critical)  $M = \frac{n}{2} + Cn^{2/3}$ : a.a.s. the largest connected component has size of order  $n^{2/3}$
- 3.- (Supercritical)  $M = cn, c > \frac{1}{2}$ : a.a.s. there is a unique component of size of order n.

Double jump in the creation of the *giant component*.

#### The problem; what was known

#### **ON THE EVOLUTION OF RANDOM GRAPHS**

by

P. ERDŐS and A. RÉNYI

Dedicated to Professor P. Turán at his 50th birthday.

We can show that for  $N(n) = \frac{n}{2} + \lambda \sqrt{n}$  with any real  $\lambda$  the probability of  $\Gamma_{n,N(n)}$  not being planar has a positive lower limit, but we cannot calculate to value. It may even be I, though this seems unlikely.

#### **PROBLEM:** Compute

$$p(\lambda) = \lim_{n \to \infty} \Pr\left\{ G\left(n, \frac{n}{2}(1 + \lambda n^{-1/3})\right) \text{ is planar} \right\}$$

What was known:

- ▶ Janson, Łuczak, Knuth, Pittel (94): 0.9870 < p(0) < 0.9997
- Luczak, Pittel, Wierman (93):  $0 < p(\lambda) < 1$

Our contribution: the whole description of  $p(\lambda)$ 

# Our result. The strategy

#### The main theorem

**Theorem (Noy, Ravelomanana, R.)** Let  $g_r(2r)$ ! be the number of cubic planar weighted multigraphs with 2r vertices. Write

$$A(y,\lambda) = \frac{e^{-\lambda^3/6}}{3^{(y+1)/3}} \sum_{k \ge 0} \frac{\left(\frac{1}{2}3^{2/3}\lambda\right)^k}{k!\,\Gamma\left((y+1-2k)/3\right)}.$$

Then the limiting probability that the random graph  $G\left(n, \frac{n}{2}(1 + \lambda n^{-1/3})\right)$  is planar is

$$p(\lambda) = \sum_{r \ge 0} \sqrt{2\pi} g_r A\left(3r + \frac{1}{2}, \lambda\right).$$

In particular, the limiting probability that  $G\left(n, \frac{n}{2}\right)$  is planar is

$$p(0) = \sum_{r \ge 0} \sqrt{\frac{2}{3}} \left(\frac{4}{3}\right)^r g_r \frac{r!}{(2r)!} \approx 0,99780.$$

#### A plot

Probability curve for planar graphs and SP-graphs (top and bottom, respectively)

The resulting multigraph is the **core** of the initial graph

# The strategy (and II): appearance in the critical window

Luczak, Pittel, Wierman (1994): the structure of a random graph in the critical window

Hence...We need to count!

### Generating Functions: algebraic methods

#### The symbolic method à la Flajolet

#### **COMBINATORIAL RELATIONS** between **CLASSES**

 $\uparrow$ 

#### EQUATIONS between GENERATING FUNCTIONS

Class	Relations
$\mathcal{C} = \mathcal{A} \cup \mathcal{B}$	C(x) = A(x) + B(x)
$\mathcal{C}=\mathcal{A} imes\mathcal{B}$	$C(x) = A(x) \cdot B(x)$
$\mathcal{C} = \operatorname{Seq}(\mathcal{B})$	$C(x) = (1 - B(x))^{-1}$
$\mathcal{C} = \operatorname{Set}(\mathcal{B})$	$C(x) = \exp(B(x))$
$\mathcal{C}=\mathcal{A}\circ\mathcal{B}$	C(x) = A(B(x))

All GF are *exponential*  $\equiv$  *labelled* objects

$$A(x) = \sum_{n \ge 0} \frac{a_n}{n!} x^n.$$

#### First application: Trees

We apply the previous grammar to count *rooted* trees

$$\mathcal{T} = \bullet \times \operatorname{Set}(\mathcal{T}) \to T(x) = x e^{T(x)}$$

To forget the root, we just integrate: (xU'(x) = T(x))

$$\int_0^x \frac{T(s)}{s} ds = \left\{ \begin{array}{c} T(s) = u \\ T'(s) \, ds = du \end{array} \right\} = \int_{T(0)}^{T(x)} 1 - u \, du = T(x) - \frac{1}{2} T(x)^2$$

and the general version

$$e^{U(x)} = e^{T(x)}e^{-\frac{1}{2}T(x)^2}$$

#### Second application: Unicyclic graphs

$$\mathcal{V} = \bigcirc_{\geq 3}(\mathcal{T}) \to V(x) = \sum_{n=3}^{\infty} \frac{1}{2} \frac{(n-1)!}{n!} (T(x))^n$$

We can write V(x) in a compact way:

$$\frac{1}{2}\left(-\log\left(1-T(x)\right)-T(x)-\frac{T(x)^2}{2}\right) \to e^{V(x)} = \frac{e^{-T(x)/2-T(x)^2/4}}{\sqrt{1-T(x)}}$$

# **Cubic planar multigraphs**

#### Planar graphs arising from cubic multigraphs

In an informal way:

$$\mathcal{G}(\bullet \leftarrow \mathcal{T}, \bullet - \bullet \leftarrow \operatorname{Seq}(\mathcal{T}))$$

#### Weighted planar cubic multigraphs

Cubic multigraphs have 2r vertices and 3r edges (Euler relation)

$$G(x,y) = \sum_{r \ge 1} \frac{g_r(2r)!}{(2r)!} x^{2r} y^{3r} = G(x^2 y^3)$$

We need to remember the number of loops and the number of multiple edges to avoid symmetries:

#### The decomposition

- ▶ We consider *rooted* multigraphs (namely, an edge is oriented).
- ▶ *Rooted* cubic planar multigraphs have the following form:

(From Bodirsky, Kang, Löffler, McDiarmid Random Cubic Planar Graphs)

#### The equations

We can relate different families of rooted cubic planar graphs between them:

G(z)	=	$\exp G_1(z)$
$3z  rac{dG_1(z)}{dz}$	=	D(z) + C(z)
B(z)	=	$\frac{z^2}{2}(D(z) + C(z)) + \frac{z^2}{2}$
C(z)	=	S(z) + P(z) + H(z) + B(z)
D(z)	=	$\frac{B(z)^2}{z^2}$
S(z)	=	$C(z)^2 - C(z)S(z)$
P(z)	=	$z^2 C(z) + \frac{1}{2} z^2 C(z)^2 + \frac{z^2}{2}$
2(1+C(z))H(z)	=	$u(z)(1 - 2u(z)) - u(z)(1 - u(z))^3$
$z^2 (C(z) + 1)^3$	=	$u(z)(1-u(z))^3.$

#### The equations: an appetizer

All GF obtained (except G(z)) are algebraic GF; for instance:

 $\begin{array}{l} 1048576\,z^{6}+1034496\,z^{4}-55296\,z^{2}+\\ \left(9437184\,z^{6}+6731264\,z^{4}-1677312\,z^{2}+55296\right)C+\\ \left(37748736\,z^{6}+18925312\,z^{4}-7913472\,z^{2}+470016\right)C^{2}+\\ \left(88080384\,z^{6}+30127104\,z^{4}-16687104\,z^{2}+1622016\right)C^{3}+\\ \left(132120576\,z^{6}+29935360\,z^{4}-19138560\,z^{2}+2928640\right)C^{4}+\\ \left(132120576\,z^{6}+19314176\,z^{4}-12429312\,z^{2}+2981888\right)C^{5}+\\ \left(88080384\,z^{6}+8112384\,z^{4}-4300800\,z^{2}+1720320\right)C^{6}+\\ \left(37748736\,z^{6}+2097152\,z^{4}-614400\,z^{2}+524288\right)C^{7}+\\ \left(9437184\,z^{6}+262144\,z^{4}+65536\right)C^{8}+1048576\,C^{9}z^{6}=0. \end{array}$ 

### Computing large powers: analytic methods

#### Singularity analysis on generating functions

GFs: analytic functions in a neighbourhood of the origin.

#### The smallest singularity of A(z) determines the asymptotics of the coefficients of A(z).

- ▶ POSITION: exponential growth  $\rho$ .
- ▶ NATURE: subexponential growth
- ▶ Transfer Theorems: Let  $\alpha \notin \{0, -1, -2, ...\}$ . If

$$A(z) = a \cdot (1 - z/\rho)^{-\alpha} + o((1 - z/\rho)^{-\alpha})$$

then

$$a_n = [z^n]A(z) \sim \frac{a}{\Gamma(\alpha)} \cdot n^{\alpha - 1} \cdot \rho^{-n}(1 + o(1))$$

#### **Our estimates**

► The excess of a graph (ex(G)) is the number of edges minus the number of vertices

$$n![z^n] \underbrace{\frac{U(z)^{n-M+r}}{(n-M+r)!} e^{-T(z)/2 - T(z)^2/4}}_{\sqrt{1-T(z)}} \underbrace{\frac{U(z)^{n-M+r}}{(1-T(z))^{3r}}}_{(1-T(z))^{3r}}$$

Where  $P_{5r}(x)$  is a polynomial of degree  $\leq 5r$ .

- ▶ We then apply a *sandwich* argument to get the estimates
- ▶ We use saddle point estimates (a la Van der Corput).

#### Without many details...

We estimate the constant using Stirling:

$$\frac{n!}{\binom{\binom{n}{2}}{M}} \frac{1}{(n-M+r)!} = \sqrt{2\pi n} \frac{2^{n-M+r}}{n^r} e^{-\lambda^3/6+3/4-n} \left(1+O\left(\frac{\lambda^4}{n^{1/3}}\right)\right)$$

For every a, we study the asymptotic behavior of

$$[z^{n}]U(z)^{n-M+r}\frac{T(z)^{a}e^{V(z)}}{(1-T(z))^{3r}} = \frac{1}{2\pi i}\oint U(z)^{n-M+r}\frac{T(z)^{a}e^{V(z)}}{(1-T(z))^{3r}}\frac{dz}{z^{n+1}}$$

We write the integrand as  $g(u) e^{nh(u)}$  (u = T(z)); relate with:

$$A(y,\lambda) = \frac{1}{2\pi i} \int_{\Pi} s^{1-y} e^{K(\lambda,s)} ds, \ K(\lambda,s) = \frac{s^3}{3} + \frac{\lambda s^2}{2} - \frac{\lambda^3}{6}$$

and  $\Pi$  is the following path in the complex plane:

$$s(t) = \begin{cases} -e^{-\pi i/3} t, & \text{for} - \infty < t \le -2, \\ 1 + it \sin \pi/3, & \text{for} - 2 \le t \le +2, \\ e^{+\pi i/3} t, & \text{for} + 2 \le t < +\infty. \end{cases}$$

Nice cancelations of  $n \dots$ 

# **Other applications**

#### General families of graphs

Many families of graphs admit an straightforward analysis:

#### (Noy, Ravelomanana, R.)

Let  $\mathcal{G} = \operatorname{Ex}(H_1, \ldots, H_k)$  and assume all the  $H_i$  are 3-connected. Let  $h_r(2r)!$  be the number of cubic multigraphs in  $\mathcal{G}$  with 2r vertices. Then the limiting probability that the random graph  $G(n, \frac{n}{2}(1 + \lambda n^{-1/3}))$  is in  $\mathcal{G}$  is

$$p_{\mathcal{G}}(\lambda) = \sum_{r \ge 0} \sqrt{2\pi} h_r A(3r + \frac{1}{2}, \lambda).$$

In particular, the limiting probability that  $G(n, \frac{n}{2})$  is in  $\mathcal{G}$  is

$$p_{\mathcal{G}}(0) = \sum_{r \ge 0} \sqrt{\frac{2}{3}} \left(\frac{4}{3}\right)^r h_r \frac{r!}{(2r)!}.$$

Moreover, for each  $\lambda$  we have

$$0 < p_{\mathcal{G}}(\lambda) < 1.$$

#### Examples...please

Some interesting families fit in the previous scheme:

- ▶  $E_x(K_4)$ :series-parallel graphs: there are not 3-connected elements in the family!
- $E_x(K_{2,3}, K_4)$ : outerplanar graphs: need to adapt the equations for cubics.
- ►  $E_x(K_{3,3})$ : The same limiting probability as planar... $K_5$  does not appear as a core!
- ▶ Many others:  $\mathsf{Ex}(K_{3,3}^+)$ ,  $\mathsf{Ex}(K_5^-)$ ,  $\mathsf{Ex}(K_2 \times K_3)$ ...

## **Further research**

#### Bipartite planar graphs and the Ising model

What about *bipartite* planar graphs in the critical window?

- ▶ Trees are always bipartite!
- Unicyclic bipartite graphs are characterized by a cycle of even lenght
- ▶ But...What about cubic multigraphs?

We need something more complicated: **ISING MODEL** 

#### A program

#### More problems (I)

Main result: structural behavior in the critical window

 $\Downarrow \downarrow \downarrow \Downarrow$ 

Can we say similar things for *planar* graphs with bounded vertex degree?

- ► Enumeration of 4-regular and {3,4}-regular planar graphs (To be done).
- Study of parameters: Airy distributions (**To be done**).
- Extend to the bipartite setting (**To be done**).

#### More problems (and II)

The asymptotic enumeration of *bipartite* planar graphs seems technically complicated (Bousquet-Mélou, Bernardi, 2009)

- Refine the grammar introduced by Chapuy, Fusy, Kang, Shoilekova, and study SP-graphs (Work in progress).
- ▶ Extend the formulas by Bousquet-Mélou, Bernardi to get the 3-connected planar components (Computationally involved!) (??)
- ▶ Study the full planar case ...
