Large-scale Mathematical Optimization

Leo Liberti, CNRS LIX Ecole Polytechnique liberti@lix.polytechnique.fr

CSC_52080_EP ex-INF580

About the course

- ▶ Aims of lectures: theory, algorithms, some code won't repeat much of MAP557
- Aims of TD: modelling abilities in practice with AMPL and Python

► Warning:

some disconnection between lectures and TD is normal

some theoretical topics do not lend themselves to implementation

- ▶ Lectures/TD: (generally) on fri afternoon
- **Exam:** mini-project (individual/pairs) or oral exam

http://www.lix.polytechnique.fr/~liberti/ teaching/dix/inf580

Motivation Basis pursuit Theoretical results Application to noisy channel encoding Improvements

Kissing Number Problem

Lower bounds Upper bounds from SDP? Gregory's upper bound Delsarte's upper bound Pfender's upper bound

Clustering in Natural Language

Clustering on graphs Clustering in Euclidean spaces Distance instability MP formulations Random projections again

What is *Mathematical Optimization*?

- ▶ Mathematics of solving optimization problems
- ► Formal language: Mathematical Programming (MP)
- ▶ Sentences: descriptions of optimization problems
- ▶ Interpreted by solution algorithms ("solvers")
- ▶ As expressive as any imperative language
- ▶ Shifts focus from *algorithmics* to *modelling*

Why Large-scale?

- ▶ Any process can be optimized
- ▶ Social, technical and business processes are complex
- ▶ Computer power limits model precision
- Nowadays, need to solve very complicated models
 increase in model size
- \blacktriangleright \Rightarrow algorithmic complexity must grow slowly with size
- ▶ Focus on fast algs and heuristics
- Investigate tractable relaxations & dimensionality reduction methods

The syllabus

- Which optimization problems can be solved? a tour of 20th century logic
- Complexity of optimization problems basics of theoretical computer science

▶ Distance geometry

modern large-scale optimization and data science techniques

▶ Random projections

new approaches to approximately solving large-scale problems

 Sparsity and l₁ minimization integrality out of continuity

► Further topics

as time allows

MP Formulations

Given functions $f, g_1, \ldots, g_m : \mathbb{Q}^n \to \mathbb{Q}$ and $Z \subseteq \{1, \ldots, n\}$

$$\begin{array}{ccc} \min_{x} & f(x) \\ \forall i \leq m & g_{i}(x) \leq 0 \\ \forall j \in Z & x_{j} \in \mathbb{Z} \end{array} \right\} \quad [P]$$

More general than it looks:

$$\begin{array}{l} & \max f(x) = -\min - f(x) \\ & \bullet \quad g_i(x) = 0 \quad \Leftrightarrow \quad (g_i(x) \le 0 \land -g_i(x) \le 0) \\ & \bullet \quad L \le x \le U \quad \Leftrightarrow \quad (L - x \le 0 \land x - U \le 0) \end{array}$$

• f, g_i represented by expression DAGs

Class of all formulations $P: \mathbb{MP}$

Semantics of MP formulations

- $\llbracket P \rrbracket$ = optimum (or optima) of P
- Given $P \in \mathbb{MP}$, there are three possibilities: [P] exists, P is unbounded, P is infeasible
- ▶ P is feasible iff [[P]] exists or P is unbounded otherwise it is infeasible
- P has an optimum iff [[P]] exists otherwise it is infeasible or unbounded

► Example:

Exercise

Code this toy MP in AMPL and solve it with BARON

Example: solution "by inspection"

10/413

Feasibility and optimality

► Feasibility problem: $[g(x) \le 0]$ can be written as the MP $[\min\{0 \mid g(x) \le 0]\}$

 Bounded MP [min{f(x) | g(x) ≤ 0}]: equivalent to feasibility (up to an ε > 0 error) bisection on f₀ in feas. prob. [g(x) ≤ 0 ∧ f(x) ≤ f₀] for max problems use [g(x) ≤ 0 ∧ f(x) ≥ f₀] instead

 Unbounded MP: not equivalent to feasibility in general, cannot prove unboundedness

Bisection algorithm

$$\blacktriangleright P \equiv \min\{f(x) \mid \forall i \in I \ g_i(x) \le 0 \land x \in X\}$$

► Assume global opt x^* of P has value $f(x^*)$ between given lower/upper bounds

• Reformulate P to a parameterized feasibility problem $Q(f_0) \equiv \{x \in X \mid f(x) \le f_0 \land \forall i \in I \ g_i(x) \le 0\}$ where $Q(f_0) = \{x \in X \mid f(x) \ge f_0 \land \forall i \in I \ g_i(x) \le 0\}$

use $Q(f_0) \equiv \{x \in X \mid f(x) \ge f_0 \land \forall i \in I \ g_i(x) \le 0\}$ for **max** problems

Bisection algorithm for min *optimal value*

- 1: Input: lower & upper bound for f_0
- 2: while lower and upper bounds differ by $> \epsilon$ do
- let f_0 be midway between bounds 3:
- if $Q(f_0)$ is feasible then 4:
- update upper bound to f_0 lower for max problems 5:

- else 6:
- 7: update *lower* bound to f_0 upper for max problems

- end if 8:
- 9: end while

solve an optimization problem with calls to feasibility oracle

• need only $\left[\log_2\left(\frac{\text{UB}-\text{LB}}{\epsilon}\right)\right]$ calls to oracle

Exercise

Solve the toy MP using this bisection algorithm in AMPL

Bisection algorithm for *minimum*

- 1: Input: lower & upper bounds for f_0 , candidate global optimum \hat{x}
- 2: while lower and upper bounds differ by $> \epsilon$ do
- let f_0 be midway between bounds 3:
- if $Q(f_0)$ is feasible then 4:
- find a feasible point x'5:
- if f(x') better than $f(\hat{x})$ then 6:
- update \hat{x} to x'7:
- update upper bound to $f(\hat{x})$ lower for max problems 8:
- end if 9:
- else 10:
- 11: update *lower* bound to f_0 upper for max problems

- end if $12 \cdot$
- 13: end while

Exercise

Solve the toy MP using this bisection algorithm in AMPL

Bisection algorithm for MP (formal)

Given:

- ▶ global optimal value approximation tolerance $\epsilon > 0$
- lower bound f, upper bound \bar{f}
- ▶ feasibility alg. \mathcal{F} that finds an element in a set or certifies \emptyset up to $\epsilon > 0$

```
1: let (\hat{x}, \hat{f}) = (\text{uninitialized}, \bar{f})
2: while \overline{f} - f > \epsilon do
3: let f_0 = (f + \bar{f})/2
4: (x', f') = \mathcal{F}(Q(f_0))
 5: if (x', f') \neq (\emptyset, \emptyset) then
 6: if f' < \hat{f} then
 7:
                update (\hat{x}, \hat{f}) \leftarrow (x', f')
                update \bar{f} \leftarrow \hat{f} or f \leftarrow \hat{f} for max problems
8:
9:
            end if
10:
       else
11:
            update f \leftarrow f_0 or \bar{f} \leftarrow f_0 for max problems
12:
         end if
13: end while
```

Subsection 1

MP language

Entities of a MP formulation

Sets of indices

- ► Parameters problem input, or *instance*
- Decision variables
 - will encode the solution after solver execution
- ► Objective function
- ► Constraints

MP Example

Linear Program (LP) in standard form \blacktriangleright m, n: number of rows and columns corresponding index sets $I = \{1, ..., m\}, J = \{1, ..., n\}$ \triangleright $c \in \mathbb{R}^n, b \in \mathbb{R}^m, A \text{ an } m \times n \text{ matrix}$ \triangleright $x \in \mathbb{R}^n$ \triangleright $\min_x c^\top x$ \triangleright $Ax = b \land x \ge 0$

Exercise

Code this example in AMPL and solve it with CPLEX

MP language implementations

► Humans model with quantifiers $(\forall, \sum,...)$ e.g. $\forall i \in I \sum_{j \in J} a_{ij}x_j \leq b_i$ structured formulation

Solution algorithms accept lists of explicit constraints e.g. $[4x_1 + 1.5x_2 + x_4 \le 2, x_1 + x_2 + x_3 + x_4 \le 1]$ flat formulation

▶ Translation from structured to flat formulation

MP language implementations
 AMPL, GAMS, Matlab+YALMIP,
 Python+amplpy/cvxpy/pyomo, Julia+JuMP, ...

Exercise

Use AMPL to derive the flat formulation from the standard form LP

AMPL

- ► AMPL = A Mathematical Programming Language
- ▶ Syntax similar to human notation
- ► Bare-bone programming language
 - e.g. no function calls
- ► Commercial & closed-source
 - extremely rapid prototyping
 - we get free licenses for this course
 - ▶ free open-source AMPL sub-dialect in GLPK glpsol
- \blacktriangleright Can also use Python+amplpy/cvxpy, or Julia+JuMP Exercise

Formulate and solve the standard form LP using Python+amplpy

Subsection 2

Solvers

Solvers

► Solver:

a solution algorithm for a whole subclass of MP examples: BARON, CPLEX

\blacktriangleright Take formulation P as input

- \blacktriangleright Output $[\![P]\!]$ and possibly other information
- ► Trade-off between generality and efficiency fast solvers for large MP subclasses: unlikely

Some subclasses of MP

- (i) LINEAR PROGRAMMING (LP) f, g_i linear, $Z = \emptyset$
- (ii) MIXED-INTEGER LP (MILP) f, g_i linear, $Z \neq \emptyset$
- (iii) Nonlinear Programming (NLP)

some nonlinearity in $f, g_i, Z = \emptyset$ f, g_i convex: convex NLP (cNLP)

(iv) MIXED-INTEGER NLP (MINLP) some nonlinearity in $f, g_i, Z \neq \emptyset$ f, g_i convex: convex MINLP (cMINLP) $\begin{array}{ccc} \min & f(x) \\ \forall i \le m & g_i(x) \le & 0 \\ \forall j \in Z & x_j \in & \mathbb{Z} \end{array} \right\} \quad [P]$

And their solvers

(i) LINEAR PROGRAMMING (LP) simplex algorithm, interior point method (IPM) Implementations: CPLEX, GLPK, CLP

- (ii) MIXED-INTEGER LP (MILP) cutting plane alg., Branch-and-Bound (BB) Implementations: CPLEX, GuRoBi
- (iii) NONLINEAR PROGRAMMING (NLP)
 IPM, gradient descent (cNLP), spatial BB (sBB)
 Implementations: IPOPT (cNLP), Baron, Couenne
- (iv) MIXED-INTEGER NLP (MINLP) outer approximation (cMINLP), sBB Implementations: Bonmin (cMINLP), Baron, Couenne

Subsection 3

MP systematics

Types of MP

$Continuous\ variables:$

- ▶ LP (linear functions)
- ▶ QP (quadratic objective over affine sets)
- ▶ QCP (linear objective over quadratic sets)
- ▶ QCQP (quadratic objective over quadratic sets)
- ▶ NLP (nonlinear functions)
- ▶ SOCP (LP over 2nd order cone)
- ► SDP (LP over PSD cone)
- ► CPP (LP over copositive cone)
- ▶ cNLP (convex sets, convex objective)

Types of MP

Mixed-integer variables:

- ▶ IP (integer programming), MIP (mixed-integer programming)
- ▶ extensions: MILP, MIQP, MIQCP, MIQCQP, cMINLP, MINLP
- ▶ BLP (LP over $\{0,1\}^n$)
- ▶ BQP (QP over $\{0,1\}^n$)

Some more "exotic" classes:

- ► MOP (multiple objective functions)
- ► BLevP (optimization constraints)
- ► SIP (semi-infinite programming) Example: nonlinear constraint $y \ge x^2$ equivalent to infinite linear constraint set $\forall p \in \mathbb{R} \ (y \ge 2px - p^2)$

Subsection 4

Some applications

Some application fields

- Production industry planning, scheduling, allocation, ...
- Transportation & logistics facility location, routing, rostering, ...
- Service industry pricing, strategy, product placement, ...
- Energy industry power flow optimization, monitoring smart grids, ...
- Machine Learning & Artificial Intelligence clustering, support vector machines, ANN training,
- Biochemistry & medicine protein structure, blending, tomography, ...
- ► Mathematics

Kissing number, packing of geometrical objects, ...

Easy example

A bank needs to invest C gazillion dollars, and focuses on two types of investments: (a) guarantees a 15% return; (b) guarantees 25%. At least one fourth of the budget C must be invested in (a), and the quantity invested in (b) cannot be more than double the quantity invested in (a). How do we choose how much to invest in (a) and (b) so that revenue is maximized?

Modelling school

Question 1: What data are we given?

Question 2: What are the decision variables?

► Parameters:

 \blacktriangleright budget C

 \blacktriangleright return on investment on (a): 15%, on (b): 25%

► Parameters:

 \blacktriangleright budget C

 \blacktriangleright return on investment on (a): 15%, on (b): 25%

Decision variables:

• $x_a =$ budget invested in (a)

•
$$x_b =$$
budget invested in (b)

► Parameters:

 \blacktriangleright budget C

 \blacktriangleright return on investment on (a): 15%, on (b): 25%

- Decision variables:
 - $x_a =$ budget invested in (a)
 - $x_b =$ budget invested in (b)
- Objective function: $1.15 x_a + 1.25 x_b$

► Parameters:

 \blacktriangleright budget C

 \blacktriangleright return on investment on (a): 15%, on (b): 25%

- Decision variables:
 - $x_a =$ budget invested in (a)
 - $x_b =$ budget invested in (b)
- Objective function: $1.15 x_a + 1.25 x_b$
- ► Constraints:

$$\begin{array}{l} \blacktriangleright \quad x_a + x_b = C \\ \blacktriangleright \quad x_a \ge C/4 \\ \blacktriangleright \quad x_b \le 2x_a \end{array}$$

Easy example: remarks

- Missing trivial constraints: verify that $x_a = C + 1$, $x_b = -1$ satisfies constraints forgot $x \ge 0$
- ► No "arbitrary" numbers in formulations: replace numbers by parameter symbols

$$\begin{array}{cccc} \max_{x_a, x_b \ge 0} & c_a x_a + c_b x_b & & \\ & x_a + x_b & = & C \\ & & x_a & \ge & pC \\ & & dx_a - x_b & \ge & 0 \end{array} \right\}$$

• Formulation generality: extend to n investments:

$$\begin{array}{cccc} \max_{x \ge 0} & \sum_{j \le n} c_j x_j & \\ & \sum_{j \le n} x_j & = & C \\ & & x_1 & \ge & pC \\ & & dx_1 - x_2 & \ge & 0 \end{array} \right\}$$

• Every parameter needs a numeric value: e.g. C = 1

Example: monitoring an electrical grid

An electricity distribution company wants to monitor certain quantities at the lines of its grid by placing measuring devices at the buses. There are three types of buses: consumer, generator, and repeater. There are five types of devices:

- ► A: installed at any bus, and monitors all incident lines (cost: 0.9MEUR)
- ▶ B: installed at consumer and repeater buses, and monitors two incident lines (cost: 0.5MEUR)
- C: installed at generator buses only, and monitors one incident line (cost: 0.3MEUR)
- D: installed at repeater buses only, and monitors one incident line (cost: 0.2MEUR)
- ► E: installed at consumer buses only, and monitors one incident line (cost: 0.3MEUR).

Provide a least-cost installation plan for the devices at the buses, so that all lines are monitored by at least one device.
Example: the electrical grid

► Index sets:

- \blacktriangleright V: set of buses v
- \blacktriangleright E: set of lines $\{u, v\}$
- A: set of *directed* lines (u, v)
- ▶ $\forall u \in V$ let N_u = buses adjacent to u
- \blacktriangleright D: set of device types
- D_M : device types covering > 1 line
- $\blacktriangleright D_1 = D \smallsetminus D_M$

► Parameters:

$$\blacktriangleright \forall v \in V \quad b_v = \text{bus type}$$

 $\blacktriangleright \quad \forall d \in D \quad c_d = \text{device cost}$

Decision variables

- $\forall d \in D, v \in V \quad x_{dv} = 1$ iff device type *d* installed at bus *v*
- ▶ $\forall d \in D, (u, v) \in A$ $y_{duv} = 1$ iff device type *d* installed at bus *u* measures line $\{u, v\}$
- ▶ all variables are binary

► Objective function

$$\min_{x,y} \sum_{d \in D} \sum_{v \in V} c_d x_{dv}$$

► Constraints

► device types:

$$\begin{array}{rcl} \forall v \in V & b_v = \operatorname{gen} & \rightarrow & x_{\mathsf{B}v} = 0 \\ \forall v \in V & b_v \in \{\operatorname{con}, \operatorname{rep}\} & \rightarrow & x_{\mathsf{C}v} = 0 \\ \forall v \in V & b_v \in \{\operatorname{gen}, \operatorname{con}\} & \rightarrow & x_{\mathsf{D}v} = 0 \\ \forall v \in V & b_v \in \{\operatorname{gen}, \operatorname{rep}\} & \rightarrow & x_{\mathsf{E}v} = 0 \end{array}$$

▶ at most one device of any type at each bus

$$\forall v \in V \quad \sum_{d \in D} x_{dv} \le 1$$

► Constraints

▶ A: every line incident to installed device is monitored

$$\forall u \in V, v \in N_u \quad y_{\mathsf{A}uv} = x_{\mathsf{A}u}$$

▶ B: two monitored lines incident to installed device

$$\forall u \in V \quad \sum_{v \in N_u} y_{\mathsf{B}uv} = \min(2, |N_u|) x_{\mathsf{B}u}$$

 \blacktriangleright C,D,E: one monitored line incident to installed device

$$\forall d \in D_1, u \in V \quad \sum_{v \in N_u} y_{duv} = x_{du}$$

line is monitored

$$\forall \{u, v\} \in E \quad \sum_{d \in D} y_{duv} + \sum_{e \in D} y_{evu} \ge 1$$

Example: solution

all lines monitored, no redundancy, cost 9.2MEUR

$$\forall P \in \mathbb{MP} \quad \mathcal{D}(P) = \begin{cases} \text{ infeasible } P \text{ is infeasible} \\ \text{unbounded } P \text{ is unbounded} \\ \llbracket P \rrbracket & \text{otherwise} \end{cases}$$

▶ I.e. does there exist a single, all-powerful solver?

Subsection 1

Formal systems

Formal systems (FS)

► A *formal system* consists of:

- \blacktriangleright an alphabet
- ▶ a formal grammar

allowing the determination of *formulæ* and *sentences*

- a set A of *axioms* (given sentences)
- ▶ a set *R* of *inference rules* allowing the derivation of new sentences from old ones
- ► A *theory T* is the smallest set of sentences that is obtained by recursively applying *R* to *A*

[Smullyan, Th. of Formal Systems, 1961]

Examples

► Alphabets:

$$\begin{split} \mathscr{B} &= \{0,1\}, \ \mathscr{N} = \mathscr{B} \cup \{2,3,\ldots,\}, \ \mathscr{V} = \{x_0,x_1,x_2,\ldots\} \\ \mathscr{E} &= \{(,),+,-,\times,\div,\Box^{\Box},\exp,\log,\sin\} \cup \ \mathscr{N} \cup \ \mathscr{V} \\ \mathscr{P} \mathscr{A}_1 &= \{\forall,\exists,\lor,\land,\lnot,=\} \cup \ \mathscr{E}, \\ \mathscr{M} \mathscr{P} &= \{\min,\max,\sum,\prod,\leq,\geq\} \cup \ \mathscr{P} \mathscr{A}_1 \end{split}$$

► An expression grammar:

expr	:	term + expr	$\mathtt{term}-\mathtt{expr}$	r term	
term	:	$\texttt{factor} \times \texttt{term}$	$factor \div ter$	rm factor	
factor	:	power	power		
power	:	$\log(\texttt{unr}) \mid \exp($	$unr) \mid sin(unr) \mid$	$(-\texttt{unr}) \mid \texttt{unr}$	
unr	:	$(expr) \mid \mathcal{N}$	V		

e.g.
$$(1 - \sin(x)^2)^{(1/2)}$$
: expr = term \rightarrow factor \rightarrow power^{power} \rightarrow unr^{unr} \rightarrow (expr)^(expr) \rightarrow (term - expr)^(term) \rightarrow (factor - term)^(factor \div factor) $\rightarrow \cdots \rightarrow (\mathcal{N} - (\sin(\mathcal{V}))^{\mathcal{N}})^{\mathcal{N} \div \mathcal{N}}$

► Axioms: see later

▶ Inference rules: modus ponens, symbol replacement, $A \vdash A \land A$, $A \vdash A \lor A$, ...

Example: PA1

- ▶ Theory: 1st order provable sentences about \mathbb{N}
- ▶ Alphabet: $+, \times, \wedge, \lor, \rightarrow, \forall, \exists, \neg, =, 0, S(\cdot)$ and variable names
- Peano's Axioms:

1.
$$\forall x \ (0 \neq S(x))$$

2. $\forall x, y \ (S(x) = S(y) \rightarrow x = y)$
3. $\forall x \ (x + 0 = x)$
4. $\forall x \ (x \times 0 = 0)$
5. $\forall x, y \ (x + S(y) = S(x + y))$
6. $\forall x, y \ (x \times S(y) = x \times y + x)$
7. axiom schema over all $(k + 1)$ -ary ϕ : $\forall y = (y_1, \dots, y_k)$
 $(\phi(0, y) \land \forall x(\phi(x, y) \rightarrow \phi(S(x), y))) \rightarrow \forall x\phi(x, y)$

► Inference: see

 $\label{eq:https://en.wikipedia.org/wiki/List_of_rules_of_inference} e.g. \ modus \ ponens \ (P \land (P \to Q)) \to Q$

► Generates ring $(\mathbb{N}, +, \times)$ and arithmetical proofs e.g. $\exists x \in \mathbb{N}^n \ \forall i \ (p_i(x) \leq 0)$ (polynomial MINLP feasibility)

Example of PA1 derivation

Thm.							
$\forall x \ (x = x)$							
Proof							
A3	$\forall x$	x + 0 = x	(1)				
logic	$\forall t, r, s$	$t = r \to (t = s \to r = s)$	(2)				
1,2	$\forall x$	$x + 0 = x \to (x + 0 = x \to x = x)$	(3)				
1, 3, mp	$\forall x$	$x + 0 = x \to x = x$	(4)				
1, 4, mp	$\forall x$	x = x	QED				

Notes:

- ▶ truth tables of $A \to B$ and $(\neg A) \lor B$ are the same
- ▶ logic indicates a "logical theorem"

[equality] $(t = r \land t = s) \rightarrow r = s$; [truth tables] $t = r \rightarrow (t = s \rightarrow r = s)$

- **mp** indicates application of *modus ponens*
- ▶ all derivations are completely syntactical

Example: Reals

- ▶ Theory: 1st order provable sentences about \mathbb{R}
- ▶ Alphabet: $+, \times, \wedge, \lor, \forall, \exists, =, <, \leq, 0, 1, variable names$
- ► Axioms: field and order
- ► Inference: see

 $\begin{aligned} &\texttt{https://en.wikipedia.org/wiki/List_of_rules_of_inference} \\ & \texttt{e.g.} \ modus \ ponens \ (P \land (P \rightarrow Q)) \rightarrow Q \end{aligned}$

• Generates polynomial rings $\mathbb{R}[X_1, \ldots, X_k]$ (for all k) e.g. $\exists x \in \mathbb{R}^n \ \forall i \ (p_i(x) \leq 0)$ (polynomial NLP feasibility)

Phrases and sentences

- ▶ Phrase: sequence of symbols generated by FS grammar e.g. x, S(x), x + 0 = x, $x \times y = z$
- Sentence: phrase, with no unquantified variable symbol, stating a relation between variables e.g. ∀x (x + 0 = x), ∀x, y ∃z (x + y = z)
- ▶ Only sentences can be *decidable*, *provable* (or *not*)

Relevance of FSs to MP

Given a FS \mathcal{F} :

- A decision problem is a set P of sentences
 Decide if a given sentence f belongs to P
- Decidability in formal systems: $P \equiv \text{provable sentences}$

- **Proof of f:** finite sequence of <u>sentences</u> ending with f<u>sentences</u>: axioms, or derived from predecessors by inference rules
- ▶ PA1: decide if sentence f about \mathbb{N} has a proof e.g. $\exists x \in \mathbb{Z}^n \ \forall i \ p_i(x) \leq 0$ (polynomial p)
- ▶ Reals: decide if sentence f about \mathbb{R} has a proof e.g. $\exists x \in \mathbb{R}^n \forall i \ p_i(x) \leq 0$ (polynomial p)
- ► Formal study of MINLP/NLP feasibility

Decidability, computability, solvability

- ▶ *Decidability*: applies to decision problems
- Computability: applies to function evaluation
 - Is the function mapping i to the i-th prime integer computable?
 - Is the function mapping Cantor's "Continuum Hypothesis" to 1 if provable in the ZFC axiom system, and to 0 otherwise, computable?
- Solvability: applies to other problems
 E.g. to optimization problems

Completeness and decidability

• Complete FS \mathcal{F} : for any $f \in \mathcal{F}$, either f or $\neg f$ is provable otherwise \mathcal{F} is *incomplete*

- $\blacktriangleright Decidable FS \mathcal{F}:$
 - \exists algorithm $\mathcal D$ s.t.

$$\forall f \in \mathcal{F} \left\{ \begin{array}{ll} \mathcal{D}(f) = 1 & \text{iff } f \text{ is provable} \\ \mathcal{D}(f) = 0 & \text{iff } f \text{ is not provable} \end{array} \right.$$

otherwise \mathcal{F} is *undecidable*

Example to underline the difference between completeness and decidability: suppose there is a FS \mathcal{F} such that

[a sentence f is provable iff it begins with the characters " $\forall x_1 \exists x_2$ "] (*) then proving completeness requires a meta-theorem to prove (*) and to show that there are no other sentences than those with given initial characters; proving decidability only requires an algorithm \mathcal{D} scanning the first few characters of f to decide provability, without actually finding a proof.

Example: PA1

- Gödel's 1st incompleteness theorem:
 PA1 is incomplete
- Turing's theorem:
 PA1 is undecidable
- $\blacktriangleright \Rightarrow \mathsf{PA1}$ is incomplete and undecidable

Subsection 2

Gödel

Gödel's 1st incompleteness theorem

- ▶ \mathcal{F} : any FS extending PA1
- **Thm.** \mathcal{F} complete iff inconsistent
- ϕ is a sentence stating $[\phi \text{ not provable in } \mathcal{F}]$ denoted $\mathcal{F} \not\vdash \phi$; it can be constructed in \mathcal{F} (hard part of thm.)
 - ▶ \vdash : "is provable" in PA1; \vdash : in meta-language
 - Assume \mathcal{F} is complete: either $\mathcal{F}\vdash\phi$ or $\mathcal{F}\vdash\neg\phi$
 - ▶ If $\mathcal{F} \vdash \phi$ then $\mathcal{F} \vdash (\mathcal{F} \nvDash \phi)$ i.e. $\mathcal{F} \nvDash \phi$, contradiction
 - ► If $\mathcal{F}\vdash\neg\phi$ then $\mathcal{F}\vdash\neg(\mathcal{F}\not\vdash\phi)$ i.e. $\mathcal{F}\vdash(\mathcal{F}\vdash\phi)$ this implies $\mathcal{F}\vdash\phi$, i.e. $\mathcal{F}\vdash(\phi\wedge\neg\phi)$, \mathcal{F} inconsistent

$\blacktriangleright Assume \mathcal{F} is inconsistent:$

Then any sentence is provable, i.e. \mathcal{F} complete <u>Proof</u>: if \mathcal{F} is inconsistent then for some P we have $P \land \neg P$; hence P and $\neg P$ both hold; since P, then for any Q we have $P \lor Q$; but since $\neg P$, then $P \lor Q$ implies that Q holds; therefore $P \land \neg P \to Q$

▶ If we want PA1 to be consistent, it must be incomplete

► Warning: $\mathcal{F} \not\vdash \phi \equiv \neg (\mathcal{F} \vdash \phi) \not\equiv \mathcal{F} \vdash \neg \phi$

Gödel's encoding

► For ψ a phrase in PA1, define a function $\lceil \psi \rceil \in \mathbb{N}$ an integer which encodes the phrase

 $called \ ``G\"odel \ number" \ of \ the \ phrase$

► 「.¬ is an injective map many ways to define 「.¬

▶ Inverse: $\langle \ulcorner \phi \urcorner \rangle = \phi$

 ϕ is the phrase corresponding to Gödel number $\ulcorner \phi \urcorner$

- ▶ Encode/decode in N any phrase of PA1
 - \Rightarrow sentences and proofs can be encoded as natural numbers

Gödel's self-referential sentence ϕ

- For integers x, y ∃g ∈ N ⟨g⟩ ≡ proof(x, y) : ⟨g⟩ is the sentence "⟨x⟩ is a proof in PA1 of the sentence ⟨y⟩"
- For integers m, n, p ∃g ∈ N g = Sost(m, n, p) :
 g encodes the phrase obtained by replacing the variable symbol having Gödel number n with the integer p in the phrase ⟨m⟩
 [this function replaces a symbol with a number in a phrase]
- ▶ Let **y** be the Gödel number of the phrase "y", i.e. **y** = $\lceil y \rceil$
- Define γ(y) ≡ ¬∃x ∈ ℕ proof(x, sost(y, y, y)): γ(y): β proof in PA1 for the sentence obtained by replacing, in the sentence ⟨y⟩, every variable symbol "y" with the integer y
- ► let $q = \lceil \gamma(y) \rceil$, consider $\phi \equiv \gamma(q)$ note $\phi \equiv \neg \exists x \in \mathbb{N} \operatorname{proof}(x, \operatorname{sost}(q, \mathbf{y}, q))$ q is a Gödel number $\in \mathbb{N}$, and y is a variable symbol ranging over \mathbb{N} : no "type mismatch"

Gödel's self-referential sentence ϕ

 $\phi \equiv \neg \exists x \in \mathbb{N} \ \mathsf{proof}(x,\mathsf{sost}(q,\mathbf{y},q))$

 \blacktriangleright Let $\psi \equiv \langle \text{sost}(q, \mathbf{v}, q) \rangle$ ψ derived by replacing phrase "y" in $\langle q \rangle$ with integer q (†) • $\phi \equiv$ "there is no proof in PA1 for ψ " • How did we obtain ϕ ? Since $\phi \equiv \gamma(q)$, ϕ derived by replacing phrase "y" in $\gamma(\mathbf{y})$ with integer $q \mid (\ddagger)$ • Only difference between ϕ and ψ : $\gamma(y)$ instead of $\langle q \rangle$ • But recall that $q = \lceil \gamma(y) \rceil$, i.e. $|\gamma(y) \equiv \langle q \rangle|$ \blacktriangleright So, in fact, $\psi \equiv \phi$ • Hence ϕ states " ϕ is not provable in PA1"

Note: replacement of y with q in meta-language (\ddagger) is encoded by sost() in PA1 (\dagger)

Subsection 3

Turing

Turing machines

- ► Turing Machine (TM): *computation model*
 - ▶ infinite tape with cells storing finite alphabet letters
 - ▶ head reads/writes/skips *i*-th cell, moves left/right
 - **•** states=program (e.g. if s write 0, move left, change to state t)
 - ▶ initial tape content: input, final tape content: output
 - ▶ final state \perp : termination (nontermination denoted \varnothing)
 - can represent operations in PA1
- ▶ \exists universal TM (UTM) U s.t.
 - input: the program of a TM T and an input x for T
 - \blacktriangleright U simulates T running on x and returns output T(x)
- \blacktriangleright \Rightarrow The basis of the modern computer
- TMs can be represented as sentences in PA1 see this proof we'll see a similar proof while discussing Cook's theorem in Ch. 3

The halting problem

 ► HALTING PROBLEM (HP): given TM M and input x, is M(x) = ⊥? i.e. does a given TM terminate on its input?

► Turing's theorem: HP is undecidable

TMs can be represented in $PA1 \Rightarrow$ so can HP

▶ HP is an undecidable sentence in PA1
 ⇒ PA1 is undecidable

Turing's theorem: Computable functions

- TM T on input x yielding output y: write T(x) = y
- If a TM T terminates on all input, $T(\cdot)$ is *computable* a.k.a. "total computable"
- ▶ If a function is not computable, then it's *uncomputable*
- If T only terminates on some input, $T(\cdot)$ is *partial computable*

Let $T(x) = \varnothing$ (undefined) if T does not terminate on input x

- Every total computable function is also (trivially) partial computable
- If a partial computable function is not total, then it is uncomputable

Turing's theorem: Proof

- ► Enumerate all TMs: $(M_j \mid j \in \mathbb{N})$
- ► Halting function halt $(i, \ell) = \begin{cases} 1 & \text{if } M_i(\ell) = \bot \\ 0 & \text{if } M_i(\ell) = \emptyset \end{cases}$
- Show halt $\neq F$ for any total computable $F(i, \ell)$:
 - define G(i) = 0 if F(i, i) = 0, and undefined (\emptyset) othw *G* is partial computable because *F* is computable
 - let M_j be the TM computing G
 ∀ input i, M_j(i) = ⊥ iff G(i) = 0 (since G(i) undefined othw)
 consider halt(j, j):
 - $\blacktriangleright \ \operatorname{halt}(j,j) = 1 \to M_j(j) = \bot \to G(j) = 0 \to F(j,j) = 0$
 - $\blacktriangleright \ \mathsf{halt}(j,j) = 0 \to M_j(j) = \varnothing \to G(j) = \varnothing \to F(j,j) \neq 0$
 - ▶ so $halt(j, j) \neq F(j, j)$ for all j
- \blacktriangleright \Rightarrow halt is not total computable
 - \Rightarrow \exists inputs on which the TM for halt does not terminate
 - $\Rightarrow \not\exists$ single terminating algorithm to solve all instances of HP

Subsection 4

Tarski

▶ Tarski's theorem: Reals is complete

► Algorithm:

constructs solution sets (YES) or contradictions (NO) \Rightarrow provides proofs or contradictions for all sentences

$\blacktriangleright \Rightarrow \mathsf{Reals} \text{ is complete and also decidable}$

(since every complete theory is decidable, see next slide)

$Completeness \Rightarrow decidability$

```
\blacktriangleright Given \phi \in \mathcal{F}
       i = 0
       while 1 do
          if proof(i, \lceil \phi \rceil) then
              return YES
          else if proof(i, \lceil \neg \phi \rceil) then
              return NO
          end if
          i = i + 1
       end while
```

• Since \mathcal{F} complete, algorithm terminates on all ϕ

Tarski's theorem

▶ Algorithm based on quantifier elimination

- ► Feasible sets of polynomial systems p(x) ≤ 0 have finitely many connected components
- ► Each connected component recursively built of cylinders over points or intervals *extremities: pts.*, ±∞, *algebraic curves at previous recursion levels*
- ▶ In some sense, generalization of Reals in \mathbb{R}^1

Dense linear orders

Given a sentence ϕ in DLO (similar to Reals in one dimension)

- ▶ Reduce to DNF w/clauses $\exists x_i q_i(x)$ where $q_i = \bigwedge q_{ij}$
- Each q_{ij} has form s = t or s < t (s, t vars or consts)
 - \blacktriangleright s,t both constants:
 - s < t, s = t verified and replaced by 1 or 0
 - s, t the same variable x_i :

s < t replaced by 0, s = t replaced by 1

• if s is x_i and t is not:

s = t means "replace x_i by t" (eliminate x_i)

▶ remaining case:

 q_i conjunction of $s < x_i$ and $x_i < t$: replace by s < t (eliminate x_i)

- ▶ q_i no longer depends on x_i , rewrite $\exists x_i q_i$ as q_i
- Repeat over vars. x_i , obtain real intervals or contradictions

Subsection 5

Completeness and incompleteness

Decidability and completeness

- ▶ PA1 is incomplete and undecidable
- ▶ Reals is complete and decidable
- ▶ Are there FS \mathcal{F} that are:
 - ▶ incomplete and decidable?
 - complete and undecidable?

this case already discussed, answer is NO
Incomplete and decidable (trivial)

NoInference:

Any FS with $<\infty$ axiom schemata and no inference rules

- ▶ Only possible proofs: sequences of axioms
- ▶ Only provable sentences: axioms
- For any other sentence f: no proof of f or $\neg f$
- Trivial decision algorithm: given f, output YES if f is a finite axiom sequence, NO otherwise
- ► NoInference is incomplete and decidable

Incomplete and decidable (nontrivial)

► ACF: Algebraically Closed Fields (e.g. C) field axioms + "every polynomial splits" schema

► Theorem: ACF is incomplete

- ACF_p: ACF \land C_p $\equiv [\sum_{j \leq p} 1 = 0]$ (with p prime)
- ▶ Claim: $\forall p \text{ (prime) } \mathsf{C}_p \text{ independent of ACF}$
 - Suppose proof of C_p or $\neg C_p$ possible for p
 - ▶ then either $ACF \land \neg C_p$ or $ACF \land C_p$ inconsistent
 - ▶ but \exists field of *any* prime characteristic *p*
 - ► \Rightarrow ACF \land C_p and ACF $\land \neg$ C_p consistent for all p

• Theorem: ACF is decidable Decision algorithm $\mathcal{D}(\psi)$ for ACF:

- if ψ is C_p or $\neg C_p$ for some prime p, return NO
- ▶ else run quantifier elimination on ψ
- $\blacktriangleright \Rightarrow \mathsf{ACF}$ is incomplete and decidable

The two meanings of *completeness*

► WARNING!!!

"complete" is used in two different ways in logic

- 1. Gödel's 1st incompleteness theorem FS \mathcal{F} complete₁ if ϕ or $\neg \phi$ provable $\forall \phi$
- 2. Gödel's completeness $_2$ theorem
 - A: set of sentences in \mathcal{F}
 - M a model of \mathcal{F} (domain of values for var symbols)
 - A^M : each var in A replaced by corresp. value
 - ▶ $\exists M \text{ s.t. } A^M \text{ is true} \Rightarrow A \text{ consistent}$

partial converse: corollary of Gödel's completeness thm

- Complete₂ FS: $\forall M(A^M) \Rightarrow \mathcal{F} \vdash A$
- ► Gödel's completeness theorem: 1st order logic is complete₂
- ▶ Note the strong assumption " $\forall M$ "

incompleteness theorem only considers $M = \mathbb{N}$

▶ Pay attention when reading literature/websites

Subsection 6

MP solvability

The issue

- Proved PA1 incomplete and undecidable
- ▶ Proved Reals complete and decidable
- ▶ But MP feasibility problems are *existential statements*

 $\exists x \text{ s.t. } g(x) \leq 0 ?$

- PA1 and Reals also involve universal quantifiers
 ⇒ MP feasibility provides smaller theories
- ► For Reals, if larger theory complete and decidable, smaller theory also complete and decidable
- ▶ For PA1, larger theory incomplete and undecidable, but smaller theory might be complete or decidable!

Polynomial equations in integers

► Consider the feasibility-only MP

 $\min\{0 \mid \forall i \le m \ g_i(x) = 0 \land x \in \mathbb{Z}^n\}$

with $g_i(x)$ multivariate polynomials in x

▶ Rewrite as a *Diophantine equation* (DE):

$$\exists x \in \mathbb{Z}^n \quad \sum_{i \le m} (g_i(x))^2 = 0 \tag{1}$$

- ► Can restrict \mathbb{Z} to \mathbb{N} wlog, i.e. Eq. (1) \in PA1 write $x_i = x_i^+ - x_i^-$ where $x_i^+, x_i^- \in \mathbb{N}^n$
- Formulæ of PA1 are generally undecidable but is the subclass (1) of PA1 decidable or not?

Hilbert's 10th problem

► Hilbert:

Given a Diophantine equation with any number of unknowns and with integer coefficients: devise a process which could determine by a finite number of operations whether the equation is solvable in integers

► Davis & Putnam: conjecture DEs are undecidable

- \blacktriangleright consider set \mathbb{RE} of *recursively enumerable* (r.e.) sets
- ▶ $R \subseteq \mathbb{N}$ is in \mathbb{RE} if \exists TM listing all and only elements in R $\mathbb{TM} = \{M : \mathbb{N} \to \mathbb{N} \mid M \text{ is a TM}\} \Rightarrow \forall R \in \mathbb{RE} \exists M_R \in \mathbb{TM} (\operatorname{ran} M_R = R)$ moreover, $\forall r \in R$ we have $M_R(r) = \bot$

▶ some \mathbb{RE} sets are undecidable, e.g. $R = \{ \ulcorner \alpha \urcorner | \mathsf{PA1} \vdash \alpha \}$ r.e.: list all proofs; undecidable: by Turing's thm "listing elements of set" different from "proving element in set"

▶ for each $R \in \mathbb{RE}$ show \exists polynomial p(r, x) s.t.

 $r \in R \leftrightarrow \exists x \in \mathbb{N}^n \ p(r, x) = 0$

▶ if we can prove this, \exists undecidable DEs othw $\forall r \in \mathbb{N}$ decide if $r \in R$ by finding $x \in \mathbb{N}^n : p(r, x) = 0$ against undecidability of PA1

Proof strategy

- Strategy: "model" r.e. sets with polynomial equations in integers
- ► D&P+Robinson: universal quantifiers removed, but eqn system involves exponentials
- Matiyasevich: exploits exponential growth of Pell's equation solutions to remove exponentials
- ► ⇒ DPRM theorem, implying DE undecidable Negative answer to Hilbert's 10th problem

Structure of the DPRM theorem

► Gödel's proof of his 1st incompleteness thm.

r.e. sets \equiv DEs with $<\infty$ \exists and bounded \forall quantifiers

▶ Davis' normal form

one bounded quantifier suffices: $\exists x_0 \forall a \leq x_0 \exists x \ p(a, x) = 0$

(2 bnd qnt \equiv 1 bnd qnt on pairs) and induction

▶ Robinson's idea

get rid of bounded universal quant. by using exponent vars

• *idea*:
$$[\exists x_0 \forall a \leq x_0 \exists x \ p(a, x) = 0]$$
 " \rightarrow " $\left[\exists x \prod_{a \leq x_0} p(a, x) = 0\right]$

precise encoding needs variables in exponents

Matyiasevic's contribution

express $c = b^a$ using polynomials

• use Pell's equation $x^2 - dy^2 = 1$

let solutions (x_n, y_n) satisfy $x_n + y_n \sqrt{d} = (x_1 + y_1 \sqrt{d})^n$

• $x_n = O(d^{n/2}) \Rightarrow$ can express exponentials with polynomials

MP is unsolvable

 ${}^{\star} \ R \in \mathbb{RE} \Rightarrow \exists M \in \mathbb{TM} \text{ s.t. ran } M = R$ by defn, now prove converse

- ▶ Lemma: $\forall M \in \mathbb{TM} \operatorname{ran} M \in \mathbb{RE}$
 - ▶ **Pf**: Consider list of all TMs $(M_i | i \in \mathbb{N})$ if $M_i(x) = \bot$ at *t*-th execution step, write $M_i^t(x) = \bot$
 - ▶ Yields all sets in $\mathbb{RE} = (R_i \mid i \in \mathbb{N})$ by dovetailing $\Rightarrow \forall k \in \mathbb{N}, t < k, i \leq t \text{ if } M_i^t(k-t) = \bot \text{ append } k-t \text{ to } R_i$ $\Rightarrow R_i = \{k-t \mid \exists k \in \mathbb{N}, t < k : M_i^t(k-t) = \bot\}$
- ▶ DPRM theorem: $\forall R \in \mathbb{RE}$, R represented by poly eqn
- ▶ By lemma, can choose UTM M_i with ran $M_i = R_i \in \mathbb{RE}$ ⇒ \exists Universal DE (UDE), say U(r, x) = 0

▶ min{0 | $U(r, x) = 0 \land x \in \mathbb{N}^n$ }: undecidable (feasibility) MP

• $\min_{x \in \mathbb{N}^n} (U(r, x))^2$: unsolvable (optimization) MP

Common misconception

"Since \mathbb{N} is contained in \mathbb{R} , how is it possible that Reals is decidable but DE (= Reals $\cap \mathbb{N}$, right?) is not?"

After all, if a problem contains a hard subproblem, it's hard by inclusion, right?

▶ Can you express $\mathsf{DE} p(x) = 0 \land x \in \mathbb{N}$ in Reals? • p(x) = 0 belongs to both DE and Reals, OK \blacktriangleright " $x \in \mathbb{N}$ " in Reals? \Leftarrow find poly q(x) s.t. $\exists x \ q(x) = 0$ iff $x \in \mathbb{N}^n$ • $q(x) = x(x-1)\cdots(x-a)$ only good for $\{0, 1, ..., a\}$ $q(x) = \prod (x-i)$ is ∞ ly long, invalid ► IMPOSSIBLE! if it were possible, DE would be decidable, contradiction ► \Rightarrow Reals \supseteq DE

MIQCP is undecidable

▶ [Jeroslow 1973]: MIQCP:

$$\begin{array}{ccc} \min & c^{\top}x \\ \forall i \le m & x^{\top}Q^{i}x + a_{i}^{\top}x + b_{i} \ge 0 \\ & x \in \mathbb{Z}^{n} \end{array} \right\} \qquad (\dagger)$$

is undecidable

Proof:

- Let U(r, x) = 0 be an UDE
- ▶ $P(r) \equiv \min\{u \mid (1-u)U(r,x) = 0 \land u \in \{0,1\} \land x \in \mathbb{Z}^n\}$ P(r) describes an unsolvable problem
- Linearize every product $x_i x_j$ by y_{ij} and add $y_{ij} = x_i x_j$ until only degree 1 and 2 left
- ▶ Obtain instances of MIQCP (†) for every r

Some MIQCQPs are decidable

- ▶ If each Q_i is diagonal PSD, decidable [Witzgall 1963]
- ▶ If x are bounded in $[x^L, x^U] \cap \mathbb{Z}^n$, decidable can express $x \in \{ \lceil x^L \rceil, \lceil x^L \rceil + 1, \dots, \lfloor x^U \rfloor \}$ by polynomial

$$\forall i \le m \quad \prod_{\substack{x_i^L \le i \le x_i^U}} (x-i) = 0$$

turn into poly system in \mathbb{R} (in Reals, decidable)

▶ \Rightarrow Bounded (vars) easier than unbounded (for Z)

 $\begin{bmatrix} \text{MIQP decision vers.} \end{bmatrix} \text{ is decidable} \\ \begin{array}{c} x^{\top}Qx + c^{\top}x &\leq \gamma \\ Ax &\geq b \\ \forall j \in Z \quad x_j \quad \in \quad \mathbb{Z} \end{bmatrix}$ (in **NP** [Del Pia et al. 2014])

NLP is undecidable

We can't represent unbounded subsets of \mathbb{N} by polynomials But we can if we allow some transcendental functions $x \in \mathbb{Z} \quad \longleftrightarrow \quad \sin(\pi x) = 0$

Constrained NLP is undecidable:

$$\min\{0 \mid U(a, x) = 0 \land \forall j \le n \ \sin(\pi x_j) = 0\}$$

• Even with just one nonlinear constraint:

$$\min\{0 \mid (U(a,x))^2 + \sum_{j \le n} (\sin(\pi x_j))^2 = 0\}$$

Unconstrained NLP is undecidable:

$$\min(U(a,x))^2 + \sum_{j \le n} (\sin(\pi x_j))^2$$

► Box-constrained NLP is undecidable (*boundedness doesn't help*): $\min\{(U(a, \tan x_1, \dots, \tan x_n))^2 + \sum_{j \le n} (\sin(\pi \tan x_j))^2 \mid -\frac{\pi}{2} \le x \le \frac{\pi}{2}\}$

Some NLPs are decidable

► All polynomial NLPs are decidable

by decidability of Reals

▶ QUADRATIC PROGRAMMING (QP) is decidable over \mathbb{Q}

$$\min \begin{array}{ccc} x^{\top}Qx & + & c^{\top}x \\ Ax & \geq & b \end{array} \right\} \qquad (P)$$

► Bricks of the proof

- ▶ if Q is PSD, $\llbracket P \rrbracket \in \mathbb{Q}$
 - 1. remove inactive constr., active are eqn, use to replace vars
 - 2. work out KKT conditions, they are linear in rational coefficients
 - 3. \Rightarrow solution is rational

∃ polytime IPM for solving P [Renegar&Shub 1992]
 unbounded case treated in [Vavasis 1990]

► \Rightarrow [QP decision version] is in NP \Rightarrow QP is decidable over \mathbb{Q}

Rationals

[Robinson 1949]: RT (1st ord. theory over Q) is undecidable

▶ [Pheidas 2000]: existential theory of Q (ERT) is open can we decide whether p(x) = 0 has solutions in Q? Boh!

▶ [Matyiasevich 1993]:

- equivalence between DEH and ERT
- ▶ DEH = [DE restricted to homogeneous polynomials]
- ▶ but we don't know whether DEH is decidable

Note that Diophantus solved DE in positive rationals

Worst-case algorithmic complexity

 Computational complexity theory: worst-case time/space taken by an algorithm to complete

▶ Given an algorithm \mathcal{A}

- e.g. to determine whether a graph G = (V, E) is connected or not
- input: G; size of input: $\nu = |V| + |E|$
- How does $cpu(\mathcal{A})$ vary with ν ?
 - $\mathsf{cpu}(\mathcal{A}) = O(\log \nu)$: logarithmic (sublinear)
 - $\operatorname{cpu}(\mathcal{A}) = O(\log^k \nu)$ for fixed k: polylogarithmic
 - ► $\mathsf{cpu}(\mathcal{A}) = O(\nu)$: linear
 - $\operatorname{cpu}(\mathcal{A}) = O(\nu^2)$: quadratic
 - $\mathsf{cpu}(\mathcal{A}) = O(\nu^k)$ for fixed k: polytime
 - $\mathsf{cpu}(\mathcal{A}) = O(2^{\nu})$: exponential
- $\blacktriangleright \text{ polytime} \leftrightarrow \text{efficient}$
- $\blacktriangleright exponential \leftrightarrow inefficient$

The " $O(\cdot)$ " calculus

$\forall f, g : \mathbb{N} \to \mathbb{N} \quad f <_O g \quad \leftrightarrow \quad \exists n \in \mathbb{N} \; \forall \nu > n \; (f(\nu) < g(\nu))$

$\forall g : \mathbb{N} \to \mathbb{N} \quad O(g) = \{f : \mathbb{N} \to \mathbb{N} \mid \exists C \in \mathbb{N} \ (f <_O Cg)\}$

 $\forall f,g:\mathbb{N}\to\mathbb{N}\quad O(f)< O(g)\quad \leftrightarrow \quad f\in O(g) \ \land \ g\not\in O(f)$

Are polytime algorithms "efficient"?

- ► Why are polynomials special?
- Many different variants of Turing Machines (TM) more tapes, more heads, ...
- ► Polytime is invariant to all definitions of TM e.g. TM with ∞ly many tapes: simulate with a single tape running along diagonals, similarly to dovetailing
- ▶ In practice, $O(\nu)$ - $O(\nu^3)$ is an acceptable range covering most practically useful efficient algorithms
- Many exponential algorithms are also usable in practice for limited sizes
- Sublinear algorithms aren't allowed to read their whole input!

Instances and problems

- ▶ An input to an algorithm \mathcal{A} : *instance*
- Collection of all inputs for A: problem in general, a problem P is an infinite set of instances
- $\blacktriangleright \mathcal{A} \text{ solves } P \text{ if } \mathcal{A} \text{ solves every instance of } P$
 - ▶ There are problems which no algorithm can solve
 - ▶ A problem can be solved by different algorithms
- Given P find complexity of best alg. \mathcal{A} solving P

 $\min_{<_{O}} \{ \mathsf{cpu}(\mathcal{A}) \mid \mathcal{A} \text{ solves } P \}$

We (generally) don't know how to search over all algs for P sometimes we can find complexity bounds

Complexity classes: **P**, **NP**

- ▶ Focus on *decision problems*: one bit of output
- ▶ If \exists polytime algorithm for P, then $P \in \mathbf{P}$
- ▶ If there is a polytime checkable *certificate* for all YES instances of P, then $P \in \boxed{\mathbf{NP}}$

e.g. SHORTEST s—t PATH WITH $\leq K$ EDGES in a graph G; path itself is a certificate: it can be checked whether it has fewer than K edges in time proportional to $K \leq |G|$

• We know $\mathbf{P} \subseteq \mathbf{NP}$:

polytime alg for P provides polysized <u>trace</u> certifying YES algorithmic trace: list of instructions with loops unfolded

▶ No-one knows whether $\mathbf{P} = \mathbf{NP}$: we think not

Examples of **NP** problems unlikely to have polytime alg: *k*-CLIQUE, SUBSET-SUM, KNAPSACK, HAMILTONIAN CYCLE, SAT

Equivalent definition of \mathbf{NP}

▶ **NP**: problems solved by *nondeterministic* polytime TM

nondeterministic: follow all paths concurrently, stop at first YES

▶ Equivalence with previous definition

(⇒) Assume ∃ polysized certificate for every YES instance. Nondeterministic polytime algorithm: concurrently explore all possible polysized certificates, call verification oracle for each, determine YES/NO.

► (⇐) Run nondeterministic polytime algorithm: trace will look like a tree (branchings at tests, loops unrolled) with polytime depth. If YES there will be a terminating polysized sequence of steps from start to termination, serving as a polysized certificate

Subsection 1

Some combinatorial problems in \mathbf{NP}

k-STABLE

• Instance: (G = (V, E), k)

 \blacktriangleright <u>Problem</u>: determine if G has a stable set of size k

- A subset $U \subseteq V$ is stable if G[U] is empty
- For G = (V, E) and $U \subseteq V$, the subgraph of G induced by U is

 $G[U] = (U, \{\{u, v\} \in E \mid u, v \in U\})$

 $\blacktriangleright \quad G = (V, E) \text{ is } empty \text{ if } E = \emptyset$

▶ 1-STABLE? YES (every graph with \geq 1 vertices is YES)

- ► 2-STABLE? YES (every non-complete graph is YES)
- ▶ 3-stable? NO

Variables? Objective? Constraints?

Variables? Objective? Constraints?

• Decision variables:
$$\forall j \in V \quad x_j = \begin{cases} 1 & j \in k \text{-stable} \\ 0 & \text{otherwise} \end{cases}$$

Variables? Objective? Constraints?

• Decision variables:
$$\forall j \in V \quad x_j = \begin{cases} 1 & j \in k \text{-stable} \\ 0 & \text{otherwise} \end{cases}$$

▶ no objective (pure feasibility MP)

Variables? Objective? Constraints?

SATISFIABILITY (SAT)

• Instance: boolean logic sentence f in CNF

 $\bigwedge_{i \le m} \bigvee_{j \in C_i} \ell_j$

where $\ell_i \in \{x_i, \bar{x}_i\}$ for $j \leq n$

• <u>Problem</u>: is there $\phi : x \to \{0, 1\}^n$ s.t. $\phi(f) = 1$?

$$f \equiv (x_1 \lor \bar{x}_2 \lor x_3) \land (\bar{x}_1 \lor x_2)$$

$$x_1 = x_2 = 1, x_3 = 0 \text{ is a YES certificate}$$

$$f \equiv (x_1 \lor x_2) \land (\bar{x}_1 \lor \bar{x}_2) \land (\bar{x}_1 \lor x_2) \land (x_1 \lor \bar{x}_2)$$

$$\frac{\phi}{\text{false}} \begin{array}{|c|c|c|c|c|c|c|c|} x = (0,0) & x = (1,0) & x = (0,1) \\ \hline c_2 & c_1 & c_3 & c_4 \end{array}$$

Variables? Objective? Constraints?

Variables? Objective? Constraints?

Algorithm $\hat{\rho}$ to generate MP from given SAT sentence $\bigwedge_{i \leq m} \bigvee_{j \in C_i} \ell_j$:

Variables? Objective? Constraints?

Algorithm $\hat{\rho}$ to generate MP from given SAT sentence $\bigwedge_{i \leq m} \bigvee_{j \in C_i} \ell_j$:

• Literals $\ell_j \in \{x_j, \bar{x}_j\}$: decision variables in $\{0, 1\}$

$$\hat{\rho}(\ell_j) \quad \longmapsto \quad \left\{ \begin{array}{cc} x_j & \text{if } \ell_j \equiv x_j \\ 1 - x_j & \text{if } \ell_j \equiv \bar{x}_j \end{array} \right.$$

• Clauses $\Gamma_i \equiv \bigvee_{j \in C_i} \ell_j$: constraints

$$\hat{\rho}(\Gamma_i) \quad \longmapsto \quad \sum_{j \in C_i} \hat{\rho}(\ell_j) \ge 1$$

► Conjunction: feasibility-only ILP

$$\hat{\rho}\left(\bigwedge_{i}\Gamma_{i}\right) \longmapsto \forall i \leq m \quad \hat{\rho}(\Gamma_{i})$$

• Algorithm $\hat{\rho}$ is called a *reduction* from SAT to ILP reductions from Q to P model Q in terms of P

AMPL code for SAT?

Using $\hat{\rho}$ we can only obtain flat formulations Example: file sat.run (flat formulation) for instance $(x_1 \lor \bar{x}_2 \lor x_3) \land (\bar{x}_1 \lor x_2)$

```
# sat.run
var x{1..3} binary;
subject to con1: x[1] + (1-x[2]) + x[3] >= 1;
subject to con2: (1-x[1])+ x[2] >= 1;
option solver cplex;
solve;
display x, solve_result;
```

Subsection 2

 $\mathbf{NP} ext{-hardness}$

NP-Hardness

- ▶ Do hard problems exist? Depends on $\mathbf{P} \neq \mathbf{NP}$
- ▶ Next best thing: define *hardest problem in* **NP**
- ▶ Defn.: Problem *P* is <u>NP-hard</u> if $\forall Q \in \mathbf{NP} \exists$ polytime alg. ρ_Q : $q \in Q \mapsto \rho_Q(q) \in P$ with q YES iff $\rho_Q(q)$ YES

 $\rho_Q:Q\to P$ is called a $polynomial\ reduction\ from\ Q$ to P

- **Prop.**: P is hardest for **NP**
 - 1. run best algorithm for P on $\rho_Q(q)$ get answer $\alpha \in \{ \mathsf{YES}, \mathsf{NO} \}$
 - 2. return α as answer for q
 - 3. so Q no harder than Psince solved Q with alg for P + polytime taken by $\rho_Q(q)$
 - 4. holds $\forall Q \in \mathbf{NP} \Rightarrow$ nothing in **NP** harder than P
- If P is in **NP** and is **NP**-hard, it is called **NP**-complete
- Reduction: model Q using language of P
- ▶ Thm. [Cook 1971]: everything in **NP** reduces to SAT

Cook's theorem

Theorem 1: If a set S of strings is accepted by some nondeterministic Turing machine within polynomial time, then S is P-reducible to {DNF tautologies}.

TM dynamics modelled with Boolean vars <u>Proposition symbols:</u>

 $\begin{array}{l} P_{s,t}^{i} \quad \text{for } 1 \leq i \leq \ell, \ l \leq s,t \leq T. \\ P_{s,t}^{i} \quad \text{is true iff tape square number s} \\ \text{at step } t \quad \text{contains the symbol } \sigma_{i} \\ Q_{t}^{i} \quad \text{for } 1 \leq i \leq r, \ l \leq t \leq T. \ Q_{t}^{i} \quad \text{is true iff at step } t \quad \text{the machine is in state } q_{i}. \end{array}$

 $S_{s,t}$ for l≤s,t≤T is true iff at time t square number s is scanned by the tape head.

Definition of TM dynamics in CNF

 B_t asserts that at time t one and only one square is scanned:

 ${}^{B}t = ({}^{S}_{1,t} \vee {}^{S}_{2,t} \vee \cdots \vee {}^{S}_{T,t})$

[& (¬S_{i,t} ∨ ¬S_{j,t})] 1≤i<j≤T

 $\begin{array}{c} {G}_{1,\,j}^t \mbox{ asserts} \\ \mbox{that if at time } t \mbox{ the machine is in} \\ \mbox{state } q_i \mbox{ scanning symbol } \sigma_j, \mbox{ then at} \\ \mbox{time } t+1 \mbox{ the machine is in state } q_k, \\ \mbox{where } q_k \mbox{ is the state given by the} \\ \mbox{transition function for } M. \end{array}$

 $\begin{array}{ccc} t & T \\ G_{i,j} &= & \begin{cases} T \\ s=1 \end{cases} (\neg Q_t^i \lor \neg S_{s,t} \lor \neg P_{s,t}^j \lor Q_{t+1}^k) \end{array}$

Description of a dynamical system using a declarative programming language (SAT) — what MP is all about!

The MP version of Cook's theorem

Thm.

Any problem P in **NP** can be polynomially reduced to a MILP

Proof

Since $P \in \mathbf{NP}$, every YES instance $\pi \in P$ must have a polynomial-time (say $\alpha^{P}(|\pi|)$) verifiable certificate c_{π} (wlog assume it is a {0,1} string), with length bounded by a polynomial (say $\beta^P(|\pi|)$). This means that a deterministic TM M_P verifying c_{π} will reach termination in polytime $\alpha^P(\pi)$. Let κ be such that $\alpha^P, \beta^P \in O(|\pi|^{\kappa})$. We define a MILP on binary variables holding the content of the tape of M_P as it changes according to the transition function of M_P , such that the tape contains: (i) "NO" in the first cell, and π in the subsequent $|\pi|$ cells, at the initial step k = 0; (ii) "YES" in the first cell at the final step $k = |\pi|^{\kappa}$. Then the MILP is feasible iff π is a YES instance of P. This provides a polytime reduction from P to MILP.

Cook's theorem: sets and params

- ▶ Model a deterministic TM dynamics using MILP
- M_P is a 5-tuple $(Q, \Sigma, s, F, \delta)$: states, alphabet, initial, final, transition
- ► Transition function $\delta : Q \smallsetminus F \times \Sigma \to Q \times \Sigma \times \{-1, 1\}$ δ : state ℓ , symbol $j \mapsto$ state ℓ' , symbol j', direction d
- M_P polytime: terminates in $|\pi| n^{\kappa}$
- ► Index sets:

states Q, characters Σ , tape cells I, steps K

► Parameters:

initial tape string (NO, π) YES written in cell 1 when M_P in final state

Cook's theorem: decision vars

∀i ∈ I, j ∈ Σ, k ∈ K t_{ijk} = 1 iff tape cell i contains symbol j at step k
∀i ∈ I, k ∈ K h_{ik} = 1 iff head is at tape cell i at step k
∀l ∈ Q, k ∈ K q_{lk} = 1 iff M_P is in state l at step k

Cook's theorem: constraints (informal)

1. Initialization:

- 1.1 initial string (NO, π) on tape at step k = 0
- 1.2 M_P in initial state s at step k = 0
- 1.3 initial head position on cell i = 0 at k = 0

2. Execution:

- 2.1 $\forall i, k$: cell *i* has exactly one symbol *j* at step *k*
- 2.2 $\forall k: M_P$ is in exactly one state ℓ
- 2.3 $\forall k$: tape head M_P is at exactly one cell i
- 2.4 $\forall i, k$: if cell *i* changes symbol between steps *k* and k + 1, head must be on cell *i* at step *k*
- 2.5 $\forall k, i, j$: cell *i* and symbol *j* in state *k* lead to cells, symbol and states given by transition function δ

3. Termination:

3.1 M_P terminates at step $k \le n^k$ w/YES written in cell 1

Cook's theorem: constraints

1. Initialization:

1.1
$$(t_{1,\text{NO},0} = 1) \land (\forall i > 1 \quad t_{i,\pi_i,0} = 1)$$

1.2 $q_{s,0} = 1$
1.3 $h_{0,0} = 1$

2. Execution:

$$\begin{array}{ll} 2.1 \quad \forall i,k \quad \sum_{j} t_{ijk} = 1 \\ 2.2 \quad \forall k \quad \sum_{\ell} q_{\ell k} = 1 \\ 2.3 \quad \forall k \quad \sum_{i} h_{ik} = 1 \\ 2.4 \quad \forall i, j \neq j', k < n^{\kappa} \quad t_{ijk} t_{i,j',k+1} \leq h_{ik} \end{array}$$

2.5
$$\forall i, \ell, \ell', j, j', k, d \text{ s.t. } (\ell', j', d) = \delta(\ell, j)$$

 $h_{ik} q_{\ell k} t_{ijk} = h_{i+d,k+1} q_{\ell',k+1} t_{i,j',k+1}$

3. Termination:

3.1
$$(t_{1,\text{YES},n^{\kappa}}=1) \land \left(\sum_{f \in F,k} q_{fk}=1\right)$$

Cook's theorem: linearization

- ▶ MP in previous slide: MINLP not MILP
- Fortet's inequalities for products of binary vars: For $x, y \in \{0, 1\}$ and $z \in [0, 1]$

 $z=xy\Leftrightarrow z\leq x\wedge z\leq y\wedge z\geq x+y-1$

- ▶ MILP is feasibility only
- ▶ MILP has polynomial size
- $\blacktriangleright \Rightarrow MILP is \mathbf{NP}$ -hard
Reduction graph

After Cook's theorem

To prove NP-hardness of a new problem P, pick a known NP-hard problem Q that "looks similar enough" to P and find a polynomial reduction ρ_Q from Q to P [Karp 1972]

Why it works: suppose P easier than Q, solve Q by calling $\operatorname{Alg}_P \circ \rho_Q$, conclude Q as easy as P, contradiction as Q hardest in **NP**

Example of polynomial reduction

- ▶ STABLE: given G = (V, E) and $k \in \mathbb{N}$, does it contain a stable set of size k?
- Assuming k-CLIQUE is **NP**-complete, reduce from it
 - Given instance (G, k) of CLIQUE consider the *complement* graph (computable in polytime)

 $\bar{G} = (V, \bar{E} = \{\{i, j\} \mid i, j \in V \land \{i, j\} \notin E\})$

- Prop.: G has clique of size k iff G has stable set of size k
 ρ(G) = G a polynomial reduction CLIQUE → STABLE
- \blacktriangleright \Rightarrow STABLE is **NP**-hard
- STABLE is also in **NP** $U \subseteq V$ is a stable set iff $E(G[U]) = \emptyset$ (polytime verification)
- \blacktriangleright \Rightarrow STABLE is **NP**-complete

Subsection 3

Complexity of solving MP formulations

LP is in ${\bf P}$

▶ Khachian's algorithm (Ellipsoid method)

▶ Karmarkar's algorithm

▶ IPM with crossover

IPM: penalize $x \ge 0$ by $-\beta \log(x)$, polysized sequence of subproblems crossover: polytime number of simplex pivots get to opt

▶ No known pivot rule makes simplex alg. polytime

- ▶ greedy pivot: exponential complexity on Klee-Minty cube
- simplex alg. polytime on uniformly random instances [Borgwardt]
- ▶ for any LP instance ∃ nearby instance on which simplex alg. is polytime [Spielman & Teng]
- ▶ ∃ randomized polytime simplex alg. [Kelner & Spielman]

(Recall) MILP is **NP**-hard

▶ SAT **NP**-hard by Cook's theorem, reduce from SAT

where ℓ_j is either x_j or $\bar{x}_j \equiv \neg x_j$

▶ Polynomial reduction $\hat{\rho}$

• E.g. $\hat{\rho}$ maps $(x_1 \lor x_2) \land (\bar{x}_2 \lor x_3)$ to

 $\min\{0 \mid x_1 + x_2 \ge 1 \land x_3 - x_2 \ge 0 \land x \in \{0, 1\}^3\}$

► SAT is **YES** iff MILP is feasible

Complexity of Quadratic Programming (QP)

$$\min \begin{array}{cc} x^{\top}Qx & + & c^{\top}x \\ Ax & \geq & b \end{array} \right\}$$

- Quadratic obj, linear constrs, continuous vars
- ▶ Many applications (e.g. portfolio selection)
- \blacktriangleright If Q has at least one negative eigenvalue, **NP**-hard
- ▶ Decision problem: "is the min. obj. fun. value ≤ 0 ?"
- ► If Q PSD then objective is convex, problem is in P KKT conditions become linear system, data in Q ⇒ soln in Q

QP is **NP**-hard

- ▶ By reduction from SAT, let σ be an instance of SAT
- ▶ $\hat{\rho}(\sigma, x) \ge 1$: linear constraints of (SAT → MILP) reduction
- ▶ Consider QP subclass

$$\min f(x) = \sum_{j \le n} x_j (1 - x_j) \\ \hat{\rho}(\sigma, x) \ge 1 \\ 0 \le x \le 1$$
 (†)

- Claim: σ is YES iff val(†) = opt. obj. fun. val. of (†) = 0
 Proof:
 - ► assume σ YES with soln. x^* , then $x^* \in \{0, 1\}^n$, hence $f(x^*) = 0$, since $f(x) \ge 0$ for all x, $\mathsf{val}(\dagger) = 0$
 - assume σ NO, suppose val(†) = 0, then (†) feasible with soln. x', since f(x') = 0 then x' ∈ {0,1}, feasible in SAT hence σ is YES, contradiction

Box-constrained QP is **NP**-hard

$$\min_{x \in [x^L, x^U]} x^\top Q x + c^\top x \bigg\}$$

 Add surplus vars v to SAT→MILP constraints: *ρ̂*(σ, x) − 1 − v = 0 (denote by ∀i ≤ m (a_i^Tx − b_i − v_i = 0))

 Consider special QP subclass

$$\min \left\{ \sum_{\substack{j \le n \\ 0 \le x \le 1, v \ge 0}} x_j (1 - x_j) + \sum_{i \le m} (a_i^\top x - b_i - v_i)^2 \right\}$$

- \blacktriangleright Issue: v not bounded above
- ▶ Reduce from 3SAT, get ≤ 3 literals per clause ⇒ can consider $0 \leq v \leq 2$

cQKP is **NP**-hard

• Continuous Quadratic Knapsack Problem (cQKP)

$$\begin{array}{rcl} \min & f(x) = x^{\top}Qx & + & c^{\top}x \\ & & \sum\limits_{j \leq n} a_j x_j & = & \gamma \\ & & x & \in & [0,1]^n, \end{array}$$

Reduction from SUBSET-SUM

given list $a \in \mathbb{Q}^n$ and γ , is there $J \subseteq \{1, \ldots, n\}$ s.t. $\sum_{j \in J} a_j = \gamma$? reduce to cQKP subclass with $f(x) = \sum_j x_j(1-x_j)$

 $\blacktriangleright \sigma$ is a YES instance of SUBSET-SUM

let
$$x_j^* = 1$$
 iff $j \in J$, $x_j^* = 0$ otherwise

feasible by construction

• f is non-negative on $[0,1]^n$ and $f(x^*) = 0$: optimum

 $\blacktriangleright \sigma$ is a NO instance of SUBSET-SUM

suppose $opt(cQKP) = x^*$ with $f(x^*) = 0$

• then $x^* \in \{0, 1\}^n$ because $f(x^*) = 0$

• feasibility of $x^* \Rightarrow J = \operatorname{supp}(x^*)$ solves σ , contradiction $\Rightarrow f(x^*) > 0$

QP on a simplex is NP-hard

$$\min f(x) = x^{\top}Qx + c^{\top}x \\ \sum_{j \le n} x_j = 1 \\ \forall j \le n \quad x_j \ge 0$$

Reduce MAX CLIQUE to subclass with $f(x) = -\sum_{\{i,j\}\in E} x_i x_j$ Motzkin-Straus Formulation (MSF):

$$\max\{\sum_{\{i,j\}\in E} x_i x_j \mid \sum_{j\in V} x_j = 1 \land x \ge 0\}$$

▶ Theorem [Motzkin& Straus 1964]

Let C be max. clique of instance $G = (V, E) \in \text{MAX CLIQUE}$, and $\omega(G) = |C|$ $\exists x^* \in \text{opt} (\text{MSF})$ with $f^* = f(x^*) = \frac{1}{2} - \frac{1}{2\omega(G)}$ $\forall j \in V \qquad x_j^* = \begin{cases} \frac{1}{\omega(G)} & \text{if } j \in C \\ 0 & \text{otherwise} \end{cases}$ Proof of the Motzkin-Straus theorem

 $x^* \in \arg(\max_{\substack{\sum_j x_j=1\\x\geq 0}} \sum_{ij\in E} x_i x_j) \text{ s.t. } |C = \{j \in V \mid x_j^* > 0\}| \text{ smallest } (\ddagger)$

1. C is a clique

Suppose $1, 2 \in C$ but $\{1, 2\} \notin E$, then $x_1^*, x_2^* > 0$, can perturb x^* by $\epsilon \in [-x_1^*, x_2^*]$, get $x^{\epsilon} = (x_1^* + \epsilon, x_2^* - \epsilon, x_3^*, x_4^*, \ldots)$, feasible w.r.t. simplex and bound constraints

{1,2} ∉ E ⇒ x₁x₂ does not appear in f(x) ⇒ f(x^ε) depends at worst linearly on ε; by local optimality of x*, f achieves max for ε = 0, in interior of its range ⇒ f(x^ε) constant w.r.t. ε. Hence f(x^ε) is globally optimal for all ε

► setting $\epsilon = -x_1^*$ or $= x_2^*$ yields global optima with more zero components than x^* , against assumption (‡), hence $\{1, 2\} \in E[C]$; by relabeling C is a clique

Proof of the Motzkin-Straus theorem

 $x^* \in \arg(\max_{\substack{\sum_j x_j = 1 \\ x \ge 0}} \sum_{ij \in E} x_i x_j) \text{ s.t. } |C = \{j \in V \mid x_j^* > 0\}| \text{ is smallest}$

2. $|C| = \omega(G)$

SO

• square the simplex constraint $\sum_j x_j = 1$, get

 $\blacktriangleright \quad \text{by construction } x_j^* = 0 \text{ for } j \notin C \Rightarrow \sum_{i < j \in C} x_i^* x_j^* = \sum_{ij \in E} x_i^* x_j^* \Rightarrow$

$$\psi(x^*) = \sum_{j \in C} (x_j^*)^2 + 2\sum_{i < j \in C} x_i^* x_j^* = \sum_{j \in C} (x_j^*)^2 + 2f(x^*) = 1$$

 $\psi(x) = 1 \text{ for all feasible } x, \text{ so } f(x) \text{ achieves maximum when } \sum_{j \in C} (x_j^*)^2 \text{ is } \\ \text{minimum, i.e. } x_j^* = \frac{1}{|C|} \text{ for all } j \in C \text{ (since } \sum_j x_j^* = 1)$

again by simplex constraint

$$2f(x^*) = 1 - \sum_{j \in C} (x_j^*)^2 = 1 - |C| \frac{1}{|C|^2} = 1 - \frac{1}{|C|} \le 1 - \frac{1}{\omega(G)}$$
$$f(x^*) \text{ attains max } \left(\frac{1}{2} - \frac{1}{2|C|}\right) \text{ when } |C| = \omega(G) \Rightarrow \forall j \in C \ x_j = \frac{1}{\omega(G)}$$

135/413

Copositive programming (CPP)

► STQP: min $x^{\top}Qx$: $\sum_{j} x_{j} = 1 \land x \ge 0$ *NP-hard by Motzkin-Straus*

• Linearize:
$$X = xx^{\top}$$

replace $x_i x_j$ by X_{ij} and add constraints $X_{ij} = x_i x_j$

- Define $A \bullet B = \operatorname{tr}(A^{\top}B) = \sum_{i,j} A_{ij}B_{ij}$ write StQP (linearized) objective as min $Q \bullet X$
- Let $C = \{X \mid X = xx^{\top} \land x \ge 0\}, \ \bar{C} = \operatorname{conv}(C)$
- $\blacktriangleright \sum_{j} x_{j} = 1 \Leftrightarrow (\sum_{j} x_{j})^{2} = 1^{2} \Leftrightarrow \mathbf{1} \bullet X = 1$
- ▶ STQP ≡ min $Q \bullet X : \mathbf{1} \bullet X = 1 \land X \in C$ linear obj. ⇒ optima attained at extrema of feas. set ⇒ can replace C by its convex hull \overline{C}

 \bar{C} is a completely positive cone

 \bar{C}^* is a copositive cone

▶ \Rightarrow A pair of **NP**-hard cNLPs!

An exercise and a project idea

You, a private investment banker, are seeing a customer. She tells you "I have 3,450,000\$ I don't need in the next three years. Invest them in low-risk assets so I get at least 2.5% return per year."

Model the problem of determining the required portfolio. Missing data are part of the fun (and of real life).

[What are the decision vars, objective, constraints? What data are missing?]

Project idea 1: Consider the MILP formulation for MAX CLIQUE and the Motzkin-Straus formulation. Can the latter have multiple global optima? If so, do they all characterize a maximum clique? What do local optima characterize? Pursue a computational study to answer these questions, then check [Gibbons et al., *Mathematics of Operations Research*, **22**:754-768, 1997] and [Pelillo & Jagota, J. Artif. Neural Networks, **2**:411-420, 1995]

Outline

Distance Geometry

The universal isometric embedding Dimension reduction Dealing with incomplete metrics The Isomap heuristic Distance geometry problem Distance geometry in MP DGP cones Barvinok's Naive Algorithm Isomap revisited

Summarv

A gem in Distance Geometry

Heron's theorem

 Heron lived around year 0

 Hung out at Alexandria's library

$$A = \sqrt{s(s-a)(s-b)(s-c)}$$

A = area of triangle
 s = ¹/₂(a + b + c)

Useful to measure areas of agricultural land

Heron's theorem: *Proof* [M. Edwards, high school student, 2007]

A. $2\alpha + 2\beta + 2\gamma = 2\pi \Rightarrow \alpha + \beta + \gamma = \pi$

 $\begin{array}{rcl} r+ix &=& ue^{i\alpha}\\ r+iy &=& ve^{i\beta}\\ r+iz &=& we^{i\gamma} \end{array}$

$$\Rightarrow (r+ix)(r+iy)(r+iz) = (uvw)e^{i(\alpha+\beta+\gamma)} = uvw e^{i\pi} = -uvw \in \mathbb{R} \Rightarrow \operatorname{Im}((r+ix)(r+iy)(r+iz)) = 0 \Rightarrow r^2(x+y+z) = xyz \Rightarrow r = \sqrt{\frac{xyz}{x+y+z}}$$

B. $s = \frac{1}{2}(a+b+c) = \frac{1}{2}(2x+2y+2z) = x+y+z$

$$s-a = x+y+z-y-z = x s-b = x+y+z-x-z = y s-c = x+y+z-x-y = z$$

 $\Rightarrow \quad \mathcal{A} = \frac{1}{2}(ra + rb + rc) = r\frac{a + b + c}{2} = rs = \sqrt{s(s - a)(s - b)(s - c)}$ 140/413

Subsection 1

The universal isometric embedding

Representing metric spaces in \mathbb{R}^n

• Given metric space (X, d) with dist. matrix (DM) $D = (d_{ij})$, embed X in some \mathbb{R}^K so it has the same DM

• Consider *i*-th row
$$x_i = (d_{i1}, \ldots, d_{in})$$
 of D

- Embed $i \in X$ by vector $U^D(i) = x_i \in \mathbb{R}^n$ define $U^D : \{1, \dots, n\} \to \mathbb{R}^n$ s.t. $U^D(i) = x_i$
- ► Thm.: $(\operatorname{ran} U^D, \ell_{\infty})$ is a metric space with DM D*i.e.* $\forall i, j \leq n ||x_i - x_j||_{\infty} = d_{ij}$
- ▶ U^D is called Universal Isometric Embedding (UIE)
- ▶ Practical issue: embedding is high-dimensional (\mathbb{R}^n)

[Kuratowski 1935]

Proof

▶ Consider i, j ∈ X with distance d(i, j) = d_{ij}
 ▶ Then

$$||x_i - x_j||_{\infty} = \max_{k \le n} |d_{ik} - d_{jk}| \le \max_{k \le n} |d_{ij}| = d_{ij}$$

ineq. \leq above from triangular inequalities in metric space:

$$\forall k \qquad d_{ik} \leq d_{ij} + d_{jk} \land d_{jk} \leq d_{ij} + d_{ik}$$

$$\Rightarrow \quad d_{ik} - d_{jk} \leq d_{ij} \land d_{jk} - d_{ik} \leq d_{ij}$$

$$\Rightarrow \quad |d_{ik} - d_{jk}| \leq d_{ij}$$

If valid $\forall k$ then valid for \max_k

▶ max $|d_{ik} - d_{jk}|$ over $k \le n$ achieved when $k \in \{i, j\}$

$$\Rightarrow \|x_i - x_j\|_{\infty} = d_{ij}$$

Subsection 2

Dimension reduction

Schoenberg's theorem

- [I. Schoenberg, Remarks to Maurice Fréchet's article "Sur la définition axiomatique d'une classe d'espaces distanciés vectoriellement applicable sur l'espace de Hilbert", Ann. Math., 1935]
- ▶ Question: Given $n \times n$ symmetric matrix D, what are necessary and sufficient conditions s.t. D is a Euclidean DM (EDM) corresponding to n points $x_1, \ldots, x_n \in \mathbb{R}^K$ with K minimum?

▶ Necessary and sufficient conditions for an EDM Thm. $D = (d_{ij})$ is an EDM iff $\frac{1}{2}(d_{1i}^2 + d_{1j}^2 - d_{ij}^2 | 2 \le i, j \le n)$ is PSD (of rank K)

 Yields important result in data science: Classic Multidimensional Scaling

Gram matrices and EDMs

- Realization: $n \times K$ matrix $x = (x_1, \ldots, x_n) \subseteq \mathbb{R}^K$
- ► Gram matrix of x: $G = xx^{\top} = (x_i \cdot x_j)$ Lemma: (i) $G \succeq 0$; (i) each $M \succeq 0$ is a Gram matrix of some x
- ▶ Theorem: given rlz x, Gram matrix G and EDM D satisfy

$$G = -\frac{1}{2}JD^2J \qquad (\S)$$

► In the theorem,
$$D^2 = (d_{ij}^2)$$
 and
 $J = I_n - \frac{1}{n} \mathbf{1} \mathbf{1}^\top = \begin{pmatrix} 1 - \frac{1}{n} & -\frac{1}{n} & \cdots & -\frac{1}{n} \\ -\frac{1}{n} & 1 - \frac{1}{n} & \cdots & -\frac{1}{n} \\ \vdots & \vdots & \ddots & \vdots \\ -\frac{1}{n} & -\frac{1}{n} & \cdots & 1 - \frac{1}{n} \end{pmatrix}$

▶ This is a variant of Schoenberg's theorem

Multidimensional scaling (MDS)

- Often get approximate EDMs D from raw data (i.e. matrices that are not EDMs, but they are "not too far") (they measure dissimilarities, discrepancies, differences)
- $\tilde{G} = -\frac{1}{2}J\tilde{D}^2J$ is an approximate Gram matrix
- Approximate Gram \Rightarrow spectral decomposition $P\tilde{\Lambda}P^{\top}$ has $\tilde{\Lambda} \not\geq 0$
- Let Λ be a PSD diagonal matrix closest to Λ̃:
 Λ obtained from Λ̃ by zeroing negative components
- $x = P\sqrt{\Lambda}$ is an "approximate realization" of \tilde{D}
- $\blacktriangleright \text{ Denote } x = \text{MDS}(D)$

Classic MDS: Main result

- 1. Prove lemma: matrix is Gram iff it is PSD
- 2. Prove theorem: $G = -\frac{1}{2}JD^2J$

Proof of lemma

$\blacktriangleright \ Gram \subseteq PSD$

- x is an $n \times K$ real matrix
- $G = xx^{\top}$ its Gram matrix
- For each $y \in \mathbb{R}^n$ (y a row vector) we have

$$yGy^{\top} = y(xx^{\top})y^{\top} = (yx)(x^{\top}y^{\top}) = (yx)(yx)^{\top} = ||yx||_2^2 \ge 0$$

 $\blacktriangleright \Rightarrow G \succeq 0$

$\blacktriangleright PSD \subseteq Gram$

- ▶ Let $G \succeq 0$ be $n \times n$
- Spectral decomposition: $G = P\Lambda P^{\top}$
 - $(P \ orthogonal, \ \Lambda \geq 0 \ diagonal)$
- $\blacktriangleright \Lambda \ge 0 \Rightarrow \sqrt{\Lambda} \in \mathbb{R}^{n \times n}$
- $G = P\Lambda P^{\top} = (P\sqrt{\Lambda})(\sqrt{\Lambda}^{\top}P^{\top}) = (P\sqrt{\Lambda})(P\sqrt{\Lambda})^{\top}$
- Let $x = P\sqrt{\Lambda}$, then G is the Gram matrix of x

Proof of theorem (1/2)

- ▶ Translate x so that centroid $\frac{1}{n} \sum_j x_j = 0$, let $G = xx^{\top}$
- Expand: $d_{ij}^2 = ||x_i x_j||_2^2 = (x_i x_j)(x_i x_j) = x_i x_i + x_j x_j 2x_i x_j$ (*)
- Aim at "inverting" (*) to express $x_i x_j$ in function of d_{ij}^2
- Sum (*) over $i: \sum_{i} d_{ij}^2 = \sum_{i} x_i x_i + n x_j x_j 2x_j \sum_{i} x_i^{0}$ by zero centroid

Similarly for j and divide by n, get:

$$\frac{1}{n} \sum_{i \le n} d_{ij}^2 = \frac{1}{n} \sum_{i \le n} x_i x_i + x_j x_j \quad (\dagger)$$

$$\frac{1}{n} \sum_{j \le n} d_{ij}^2 = x_i x_i + \frac{1}{n} \sum_{j \le n} x_j x_j \quad (\ddagger)$$

Sum (\dagger) over j, get:

$$\frac{1}{n}\sum_{i,j}d_{ij}^{2} = n\frac{1}{n}\sum_{i}x_{i}x_{i} + \sum_{j}x_{j}x_{j} = 2\sum_{i}x_{i}x_{i}$$

 \blacktriangleright Divide by n, get:

$$\frac{1}{n^2} \sum_{i,j} d_{ij}^2 = \frac{2}{n} \sum_i x_i x_i \quad (**)$$

Proof of theorem (2/2)

• Rearrange (*), (\dagger) , (\ddagger) as follows:

$$2x_i x_j = x_i x_i + x_j x_j - d_{ij}^2$$
(5)

$$x_{i}x_{i} = \frac{1}{n}\sum_{j}d_{ij}^{2} - \frac{1}{n}\sum_{j}x_{j}x_{j}$$
(6)

$$x_j x_j = \frac{1}{n} \sum_{i} d_{ij}^2 - \frac{1}{n} \sum_{i} x_i x_i$$
(7)

Replace LHS of Eq. (6)-(7) in RHS of Eq. (5), get

$$2x_i x_j = \frac{1}{n} \sum_k d_{ik}^2 + \frac{1}{n} \sum_k d_{kj}^2 - d_{ij}^2 - \frac{2}{n} \sum_k x_k x_k$$

• By (**) replace $\frac{2}{n} \sum_{i} x_i x_i$ with $\frac{1}{n^2} \sum_{i,j} d_{ij}^2$, get

$$2x_i x_j = \frac{1}{n} \sum_k (d_{ik}^2 + d_{kj}^2) - d_{ij}^2 - \frac{1}{n^2} \sum_{h,k} d_{hk}^2 \quad (\S)$$

which expresses $x_i x_j$ in function of D

Finally, show RHS of (§) is (i, j)-th entry of $-JD^2J$ See lecture notes, Thm. 10.3.5

Principal Component Analysis (PCA)

- $\blacktriangleright\,$ Given an approximate EDM D
- find x = MDS(D)
- However, you want $x = P\sqrt{\Lambda}$ in K dimensions $but \operatorname{rank}(\Lambda) > K$
- Only keep K largest components of Λ zero the rest
- ▶ Get realization in desired space
- $\blacktriangleright \text{ Denote } x = \text{PCA}(D, K)$

Example 3/3

Subsection 3

Dealing with incomplete metrics

Partial metrics

- ▶ If your metric space is missing some distances
- \blacktriangleright Get incomplete EDM D
- Cannot define vectors $U^D(i)$ in UIE
- ▶ <u>Note</u>: D defines a graph

• Complete graph with shortest path (SP) distances: $d_{24} = 2$

Floyd-Warshall algorithm 1/2

- Given n × n partial matrix D computes all shortest path lengths
- For each triplet z, u, v of vertices in the graph, test: when going $u \rightarrow v$, is it convenient to pass through z?

- ▶ If so, then change the path length
- Complete missing entries d_{uv} in D shortest path lengths $u \to v$
- Denote $\overline{D} = \text{FloydWarshall}(D)$

Floyd-Warshall algorithm 2/2

initialization for u < n, v < n do if $d_{uv} = ?$ then $d_{uv} \leftarrow \infty$ end if end for # main loop (outer loop must be on triangulation vertex) for $z \leq n$ do for u < n do for v < n do if $d_{uv} > d_{uz} + d_{zv}$ then $d_{uv} \leftarrow d_{uz} + d_{zv}$ end if end for end for end for
Subsection 4

The Isomap heuristic

Isomap embedding in \mathbb{R}^K

▶ Intuition of why it works well:

 $\blacktriangleright \text{ Denote } x = \text{Isomap}(D, K)$

[Tenenbaum et al., Science, 2000]

Subsection 5

Distance geometry problem

The Distance Geometry Problem (DGP)

Given $K \in \mathbb{N}$ and G = (V, E, d) with $d : E \to \mathbb{R}_+$, find $x : V \to \mathbb{R}^K$ s.t.

$$\forall \{i, j\} \in E \quad ||x_i - x_j||_2^2 = d_{ij}^2$$

Some applications

- clock synchronization (K = 1)
- sensor network localization (K = 2)
- molecular structure from distance data (K = 3)
- autonomous underwater vehicles (K = 3)
- EDM completion (whatever K)
- finding graph embeddings (whatever K)

Clock synchronization

From [Singer, Appl. Comput. Harmon. Anal. 2011]

Determine a set of unknown timestamps from partial measurements of their time differences

- $\blacktriangleright K = 1$
- \blacktriangleright V: timestamps
- ▶ $\{u, v\} \in E$ if known time difference between u, v
- \blacktriangleright d: values of the time differences

Used in time synchronization of distributed networks

Clock synchronization

Sensor network localization

From [Yemini, Proc. CDSN, 1978]

The positioning problem arises when it is necessary to locate a set of geographically distributed objects using measurements of the distances between some object pairs

$\blacktriangleright K = 2$

- \blacktriangleright V: (mobile) sensors
- ▶ $\{u, v\} \in E$ iff distance between u, v is measured
- \blacktriangleright d: distance values

Used whenever GPS not viable (e.g. underwater) $d_{uv} \lesssim \text{battery consumption in P2P communication betw. } u, v$

Sensor network localization

Molecular structure from distance data

From [Liberti et al., SIAM Rev., 2014]

- \blacktriangleright V: atoms
- $\{u, v\} \in E$ iff distance between u, v is known
- \blacktriangleright d: distance values

Used whenever X-ray crystallography does not apply (e.g. liquid) Covalent bond lengths and angles known precisely Distances ≤ 5.5 measured approximately by NMR

Graph embeddings

- Relational knowledge best represented by graphs
- ▶ We have fast algorithms for clustering vectors
- **Task**: represent a graph in \mathbb{R}^n
- "Graph embeddings" and "distance geometry": almost synonyms
- ▶ Used in Natural Language Processing (NLP) obtain "word vectors" & "sentence vectors"

Project idea 2: create a graph-of-words from a sentence, enrich it with semantic distances, then use the DG methods in these lectures to embed the graph in a low-dimensional space; then evaluate sentence similarity using vector angles

Complexity

▶ DGP₁ with $d: E \to \mathbb{Q}_+$ is in **NP**

- ▶ if instance YES \exists realization $x \in \mathbb{R}^{n \times 1}$
- if some component $x_i \notin \mathbb{Q}$ translate x so $x_i \in \mathbb{Q}$

 \triangleright consider some other x_i

• let
$$\ell = |\text{sh. path } p : i \to j| = \sum_{\{u,v\} \in p} (-1)^{s_{uv}} d_{uv} \in \mathbb{Q}$$

for some $s_{uv} \in \{0, 1\}$

• then
$$x_j = x_i \pm \ell \to x_j \in \mathbb{Q} \ (\forall j)$$

 \blacktriangleright \Rightarrow polytime verification of

$$\forall \{i, j\} \in E \quad |x_i - x_j| = d_{ij}$$

▶ DGP_K may not be in NP for K > 1don't know how to polytime check $||x_i - x_j||_2 = d_{ij}$ for $x \notin \mathbb{Q}^{nK}$

Hardness

PARTITION is NP-hard

Given
$$a = (a_1, \ldots, a_n) \in \mathbb{N}^n$$
, $\exists I \subseteq \{1, \ldots, n\}$ s.t. $\sum_{i \in I} a_i = \sum_{i \notin I} a_i$?

▶ Reduce PARTITION to DGP_1 on single-cycle graphs

$$\bullet a \longrightarrow \text{cycle } C$$
$$V(C) = \{1, \dots, n\}, E(C) = \{\{1, 2\}, \dots, \{n, 1\}\}$$

For
$$i < n$$
 let $d_{i,i+1} = a_i$
For $i = n$, let $d_{n,n+1} = d_{n1} = a_n$

• E.g. for
$$a = (1, 4, 1, 3, 3)$$
, get cycle graph:

[Saxe, 1979]

PARTITION is $YES \Rightarrow DGP_1$ is YES

• Given:
$$I \subset \{1, \ldots, n\}$$
 s.t. $\sum_{i \in I} a_i = \sum_{i \notin I} a_i$

Construct: realization x of C in \mathbb{R}

- 1. $x_1 = 0$ // start
- 2. **induction step**: suppose x_i known if $i \in I$

let
$$x_{i+1} = x_i + d_{i,i+1}$$
 // go right else

let
$$x_{i+1} = x_i - d_{i,i+1}$$
 // go left

• Correctness proof: by the same induction
but careful when
$$i = n$$
: have to show $x_{n+1} = x_1$

PARTITION is $YES \Rightarrow DGP_1$ is YES

Proof that $x_{n+1} = x_1$:

$$(1) = \sum_{i \in I} (x_{i+1} - x_i) = \sum_{i \in I} d_{i,i+1} =$$
$$= \sum_{i \in I} a_i = \sum_{i \notin I} a_i =$$
$$= \sum_{i \notin I} d_{i,i+1} = \sum_{i \notin I} (x_i - x_{i+1}) = (2)$$

$$(1) = (2) \Rightarrow \sum_{i \in I} (x_{i+1} - x_i) = \sum_{i \notin I} (x_i - x_{i+1}) \Rightarrow \sum_{i \le n} (x_{i+1} - x_i) = 0$$

$$\Rightarrow (x_{n+1} - x_n) + (x_n - x_{n-1}) + \dots + (x_3 - x_2) + (x_2 - x_1) = 0$$

$$\Rightarrow x_{n+1} = x_1$$

PARTITION is $NO \Rightarrow DGP_1$ is NO

▶ By contradiction: suppose DGP_1 is YES, x realization of C

►
$$F = \{\{u, v\} \in E(C) \mid x_u \le x_v\},\ E(C) \smallsetminus F = \{\{u, v\} \in E(C) \mid x_u > x_v\}$$

Trace x_1, \ldots, x_n : follow edges in $F(\rightarrow)$ and in $E(C) \smallsetminus F(\leftarrow)$

► Let
$$J = \{i < n \mid \{i, i+1\} \in F\} \cup \{n \mid \{n, 1\} \in F\}$$

⇒ $\sum_{i \in J} a_i = \sum_{i \notin J} a_i$

 \blacktriangleright So J solves Partition instance, contradiction

▶ \Rightarrow DGP is **NP**-hard, DGP₁ is **NP**-complete

Number of solutions

- \blacktriangleright (G, K): DGP instance
- $\blacktriangleright \tilde{X} \subseteq \mathbb{R}^{Kn}: \text{ set of solutions}$
- Congruence: composition of translations, rotations, reflections
- $\blacktriangleright C = \text{set of congruences in } \mathbb{R}^K$
- ► $x \sim y$ means $\exists \rho \in C \ (y = \rho x)$: distances in x are preserved in y through ρ
- $\blacktriangleright \Rightarrow \text{if } |\tilde{X}| > 0, \, |\tilde{X}| = 2^{\aleph_0}$

Number of solutions modulo congruences

• Congruence is an *equivalence relation* \sim on \tilde{X} (reflexive, symmetric, transitive)

- ▶ Partitions \tilde{X} into equivalence classes
- $\blacktriangleright X = \tilde{X} / \! \sim$

sets of representatives of equivalence classes

Focus on |X| rather than $|\tilde{X}|$

Rigidity, flexibility and |X|

- $\blacktriangleright \text{ infeasible } \Leftrightarrow |X| = 0$
- ▶ rigid graph $\Leftrightarrow |X| < \aleph_0$
- ▶ globally rigid graph $\Leftrightarrow |X| = 1$
- flexible graph $\Leftrightarrow |X| = 2^{\aleph_0}$
- ► $|X| = \aleph_0$: impossible by Milnor's theorem

Milnor's theorem implies $|X| \neq \aleph_0$

▶ System S of polynomial equations of degree 2

$$\forall i \le m \quad p_i(x_1, \dots, x_{nK}) = 0$$

• Let X be the set of $x \in \mathbb{R}^{nK}$ satisfying S

- Number of connected components of X is O(3^{nK})
 [Milnor 1964]
- ▶ Assume |X| is countable; then G cannot be flexible
 ⇒ each incongruent rlz is in a separate component
 ⇒ by Milnor's theorem, there's finitely many of them

Examples

 $V^1 = \{1, 2, 3\}$ $E^1 = \{\{u, v\} \mid u < v\}$ $d^1 = 1$

$$V^{2} = V^{1} \cup \{4\}$$

$$E^{2} = E^{1} \cup \{\{1,4\},\{2,4\}\}$$

$$d^{2} = 1 \land d_{14} = \sqrt{2}$$

$$\begin{split} V^3 &= V^2 \\ E^3 &= \{\{u, u+1\} | u \leq 3\} \cup \{1, 4\} \\ d^1 &= 1 \end{split}$$

 ρ congruence in \mathbb{R}^2 $\Rightarrow \rho x$ valid realization |X| = 1

 ρ reflects x_4 wrt $\overline{x_1, x_2}$ $\Rightarrow \rho x$ valid realization $|X| = 2 (\triangle, \bigcirc)$

 ρ rotates $\overline{x_2 x_3}$, $\overline{x_1 x_4}$ by θ $\Rightarrow \rho x$ valid realization |X| is uncountable $(\Box, \Box, \Box, \Box, \cdots, \cdots)$

Subsection 6

Distance geometry in MP

DGP formulations and methods

- System of equations
- ▶ Unconstrained global optimization (GO)
- Constrained global optimization
- ▶ SDP relaxations and their properties
- ▶ Diagonal dominance
- ▶ Concentration of measure in SDP
- ▶ Isomap for DGP

System of quadratic equations

$$\forall \{u, v\} \in E \quad \|x_u - x_v\|^2 = d_{uv}^2 \tag{8}$$

Computationally: useless reformulate using slacks:

$$\min_{x,s} \left\{ \sum_{\{u,v\}\in E} s_{uv}^2 \mid \forall \{u,v\} \in E \quad \|x_u - x_v\|^2 = d_{uv}^2 + s_{uv} \right\}$$
(9)

Unconstrained Global Optimization

$$\min_{x} \sum_{\{u,v\}\in E} (\|x_u - x_v\|^2 - d_{uv}^2)^2 \tag{10}$$

Globally optimal obj. fun. value of (10) is 0 iff x solves (8)

Computational experiments in [Liberti et al., 2006]:

- ► GO solvers from >15 years ago
- ▶ randomly generated protein data: ≤ 50 atoms
- cubic crystallographic grids: ≤ 64 atoms

Constrained global optimization

$$\min_{x} \sum_{\{u,v\} \in E} |||x_u - x_v||^2 - d_{uv}^2| \text{ exactly reformulates (8)}$$

► Relax objective f to concave part, remove constant term, rewrite min -f as $-\max f$ $\min_x \sum_{uv} (d_{uv}^2 - \|x_u - x_v\|_2^2) = \sum_{uv} d_{uv}^2 - \max_x \sum_{uv} \|x_u - x_v\|_2^2$

- Reformulate convex part of obj. fun. to convex constraints $\forall \{u, v\} \in E ||x_u x_v||_2^2 \le d_{uv}^2$
- ► Exact reformulation ("push-and-pull")

$$\max_{\substack{\{u,v\} \in E \\ \forall \{u,v\} \in E \\ \|x_u - x_v\|^2 \le d_{uv}^2 } }$$
 (11)

Theorem (Activity) At a glob. opt. x^* of a YES instance, all constraints of (11) are active

Push-and-pull linearization

Linearization of nonlinear terms $||x_i - x_j||_2^2$ for all $\{i, j\} \in E$:

$$\Rightarrow \quad \forall \{i, j\} \in E \quad \|x_i\|_2^2 + \|x_j\|_2^2 - 2x_i \cdot x_j = d_{ij}^2$$
$$\Rightarrow \begin{cases} \forall \{i, j\} \in E \quad X_{ii} + X_{jj} - 2X_{ij} = d_{ij}^2 \\ X = x x^\top \end{cases}$$

Relaxation

$$\begin{array}{rcl} X &=& x \, x^{\top} \\ \Rightarrow & X - x \, x^{\top} &=& 0 \\ (\text{relax}) &\Rightarrow & X - x \, x^{\top} &\succeq& 0 \\ \\ \text{Schur}(X, x) = \left(\begin{array}{cc} I_K & x^{\top} \\ x & X \end{array} \right) &\succeq& 0 \end{array}$$

If x does not appear elsewhere \Rightarrow get rid of it (e.g. choose x = 0):

replace $\mathsf{Schur}(X, x) \succeq 0$ *by* $X \succeq 0$

SDP relaxation

► Relaxation:

$$\min F \bullet X$$

$$\forall \{i, j\} \in E \quad X_{ii} + X_{jj} - 2X_{ij} = d_{ij}^2$$

$$X \succeq 0$$

- ▶ Note SDP \equiv linear obj. s.t. linear constrs \land PSD cone
- ▶ DGP linearization/relaxation only defines feasible set
- Note $F \bullet X = \operatorname{tr}(F^{\top}X) = \sum_{ij} F_{ij}X_{ij}$
- \blacktriangleright Can we choose a "good" objective function F?

Some possible objective functions

▶ For protein conformation:

$$\min\sum_{\{i,j\}\in E} (X_{ii} + X_{jj} - 2X_{ij})$$

with = changed to \geq in constraints (or max and \leq) "push-and-pull" relaxation

▶ [Ye, 2003], application to wireless sensors localization

$\min \operatorname{tr}(X)$

 $\begin{aligned} \operatorname{tr}(X) &= \operatorname{tr}(P^{-1}\Lambda P) = \operatorname{tr}(P^{-1}P\Lambda) = \operatorname{tr}(\Lambda) = \sum_i \lambda_i \\ &\Rightarrow \ hope \ to \ minimize \ rank \end{aligned}$

▶ How about "just random"?

How do you choose?

for want of some better criterion...

TEST!

- Download protein files from Protein Data Bank (PDB) they contain atom realizations
- Mimick a Nuclear Magnetic Resonance experiment Keep only pairwise distances < 5.5
- Try and reconstruct the protein shape from those weighted graphs
- Quality evaluation of results:

Empirical choice

- ▶ Ye faster but often imprecise
- ► *Random* good but nondeterministic
- ▶ Push-and-Pull: can relax $X_{ii} + X_{jj} 2X_{ij} = d_{ij}^2$ to $X_{ii} + X_{jj} - 2X_{ij} \ge d_{ij}^2$ easier to satisfy feasibility, useful later on
- Heuristic: add $+\eta tr(X)$ to objective, with $\eta \ll 1$ might help minimize solution rank

• $\min \sum_{\{i,j\}\in E} (X_{ii} + X_{jj} - 2X_{ij}) + \eta \operatorname{tr}(X)$ appears to be a good objective function

Retrieving realizations in \mathbb{R}^{K}

- ▶ SDP relaxation yields $n \times n$ PSD matrix X^*
- We need $n \times K$ realization matrix x^*
- $\blacktriangleright \text{ Recall } PSD \Leftrightarrow Gram$
- ▶ Apply PCA to X^* , keep K largest comps, get x'
- ▶ This yields solutions with errors
- Use x' as starting pt for local NLP solver

Later on: Barvinok's Naive Algorithm, an SDP-specific alternative to PCA

When SDP solvers hit their size limit

- ▶ SDP solver: technological bottleneck
- ▶ Can we use an LP solver instead?
- ▶ Diagonally Dominant (DD) matrices are PSD
- ▶ Not vice versa: inner approximate PSD cone $Y \succeq 0$
- ▶ Idea by A.A. Ahmadi [Ahmadi & Hall 2015]

Diagonally dominant matrices

 $n \times n$ symmetric matrix X is DD if

$$\forall i \le n \quad X_{ii} \ge \sum_{j \ne i} |X_{ij}|.$$

E.g.

(1	0.1	-0.2	0	0.04	0	
	0.1	1	-0.05	0.1	0	0	
	-0.2	-0.05	1	0.1	0.01	0	
	0	0.1	0.1	1	0.2	0.3	
	0.04	0	0.01	0.2	1	-0.3	
	0	0	0	0.3	-0.3	1	/

Gershgorin's circle theorem

• Let A be symmetric $n \times n$

 $\blacktriangleright \quad \forall i \le n \text{ let } R_i = \sum_{j \ne i} |A_{ij}| \text{ and } I_i = [A_{ii} - R_i, A_{ii} + R_i]$

► Then $\forall \lambda$ eigenvalue of $A \quad \exists i \leq n \text{ s.t. } \lambda \in I_i$ <u>*Proof*</u>

- Let λ be an eigenvalue of A with eigenvector y
- ▶ Normalize y s.t. $\exists i \leq n \ y_i = 1$ and $\forall j \neq i \ |y_j| \leq 1$ let $i = \arg \max_j |y_j|$, divide y by $\operatorname{sgn}(y_i)|y_i|$. Now fix i:

$$\blacktriangleright Ay = \lambda y \Rightarrow \sum_{j \le n: j \ne i} A_{ij} y_j + A_{ii} y_i = \sum_{j \le n: j \ne i} A_{ij} y_j + A_{ii} = \lambda y_i = \lambda$$

• Hence
$$\sum_{j \le n: j \ne i} A_{ij} y_j = \lambda - A_{ii}$$

► Triangle+Cauchy-Schwarz inequalities & $\forall j \neq i |y_j| \leq 1 \Rightarrow$ $|\lambda - A_{ii}| = |\sum_{\substack{j \leq n: j \neq i}} A_{ij}y_j| \leq \sum_{\substack{j \leq n: j \neq i}} |A_{ij}| |y_j| \leq \sum_{\substack{j \leq n: j \neq i}} |A_{ij}| = R_i$ hence $\lambda \in I_i$
$\mathrm{DD} \Rightarrow \mathrm{PSD}$

- ► Assume A is DD, λ an eigenvalue of A
- $\blacktriangleright \Rightarrow \forall i \le n \quad A_{ii} \ge \sum_{j \ne i} |A_{ij}| = R_i$

$$\blacktriangleright \Rightarrow \forall i \le n \quad A_{ii} - R_i \ge 0$$

- ▶ By Gershgorin's circle theorem $\lambda \ge 0$
- $\blacktriangleright \Rightarrow A \text{ is PSD}$

DD Linearization

$$\forall i \le n \quad X_{ii} \ge \sum_{j \ne i} |X_{ij}| \tag{*}$$

▶ linearize | · | by additional matrix var T
 ⇒ write |X| as T
 ▶ ⇒ (*) becomes

$$X_{ii} \ge \sum_{j \ne i} T_{ij}$$

add "sandwich" constraints -T ≤ X ≤ T
Can easily prove (*) in case X ≥ 0 or X ≤ 0:

$$\begin{aligned} X &\geq 0 \Rightarrow X_{ii} \geq \sum_{j \neq i} T_{ij} \geq \sum_{j \neq i} X_{ij} = \sum_{j \neq i} |X_{ij}| \\ X &\leq 0 \Rightarrow X_{ii} \geq \sum_{j \neq i} T_{ij} \geq \sum_{j \neq i} -X_{ij} = \sum_{j \neq i} |X_{ij}| \end{aligned}$$

DD Linearization: the general case

Thm.
Let:

$$\mathcal{D} = \{X \mid \forall i \leq n \ (X_{ii} \geq \sum_{j \neq i} |X_{ij}|)\}$$

$$\mathcal{T} = \{X \mid \exists T \ (\forall i \leq n \ X_{ii} \geq \sum_{j \neq i} T_{ij} \land -T \leq X \leq T)\}$$
Then $\mathcal{D} = \mathcal{T}$
Proof
(\Rightarrow) let $T = |X|$, then $\mathcal{T} = \mathcal{D}$, hence $\mathcal{D} \subseteq \mathcal{T}$
(\Leftarrow) consider \mathcal{T} :
 $\mathbf{from} \ -T \leq X \leq T$ we have $\forall i \neq j \ (-T_{ij} \leq X_{ij} \leq T_{ij})$
 $\mathbf{fthen} \ -T_{ij} \leq X_{ij} \text{ implies } T_{ij} \geq -X_{ij} \ (\star)$
 $\mathbf{by} \ (\star) \text{ and } X_{ij} \leq T_{ij} \text{ we have } T_{ij} \geq |X_{ij}|$
 $\mathbf{therefore} \ \forall i \leq n \ (X_{ii} \geq \sum_{j \neq i} T_{ij} \geq \sum_{j \neq i} |X_{ij}|) \text{ i.e. } \mathcal{T} \subseteq \mathcal{D}$
whence $\mathcal{D} = \mathcal{T}$ as claimed

DD Programming (DDP)

$$\forall \{i, j\} \in E \quad X_{ii} + X_{jj} - 2X_{ij} = d_{ij}^2 \\ X \quad \text{is DD}$$

$$\Rightarrow \begin{cases} \forall \{i, j\} \in E \quad X_{ii} + X_{jj} - 2X_{ij} = d_{ij}^2 \\ \forall i \leq n \qquad \sum_{\substack{j \leq n \\ j \neq i}} T_{ij} \leq X_{ii} \\ -T \leq X \leq T \end{cases}$$

The issue with inner approximations

DDP could be infeasible!

Exploit push-and-pull

▶ Enlarge the feasible region

► From

$$\forall \{i, j\} \in E \quad X_{ii} + X_{jj} - 2X_{ij} = d_{ij}^2$$

▶ Use "push" objective min $\sum_{ij \in E} X_{ii} + X_{jj} - 2X_{ij}$

▶ Relax to

$$\forall \{i, j\} \in E \quad X_{ii} + X_{jj} - 2X_{ij} \ge d_{ij}^2$$

Hope to achieve LP feasibility

DDP formulation for the DGP

$$\min \sum_{\substack{\{i,j\}\in E}} (X_{ii} + X_{jj} - 2X_{ij}) \\ \forall \{i,j\}\in E \qquad X_{ii} + X_{jj} - 2X_{ij} \geq d_{ij}^2 \\ \forall i \leq n \qquad \sum_{\substack{j\leq n \\ j\neq i}} T_{ij} \leq X_{ii} \\ -T \leq X \leq T$$

Solve, then retrieve solution in \mathbb{R}^{K} with PCA

Subsection 7

DGP cones

Cones

 \blacktriangleright Set C is a cone if: $\forall A, B \in C, \ \alpha, \beta \geq 0 \quad \alpha A + \beta B \in C$ \blacktriangleright If C is a cone, the *dual cone* is $C^* = \{ y \mid \forall x \in C \ \langle x, y \rangle > 0 \}$ vectors making acute angles with all elements of C▶ If $C \subset \mathbb{S}_n$ (set $n \times n$ symmetric matrices) $C^* = \{Y \mid \forall X \in C \ (Y \bullet X > 0)\}$

• A $n \times n$ matrix cone C is finitely generated by $\mathcal{X} \subset \mathbb{R}^n$ if $\mathcal{X} = \{x_1, \dots, x_p\} \land \quad \forall X \in C \ \exists \delta \in \mathbb{R}^p_+ \ X = \sum_{\ell \le p} \delta_\ell \ x_\ell x_\ell^\top$

Representations of \mathbb{DD}

► Consider $E_{ii}, E_{ij}^+, E_{ij}^-$ in \mathbb{S}_n Define $\mathcal{E}_0 = \{E_{ii} \mid i \le n\}, \mathcal{E}_1 = \{E_{ij}^\pm \mid i < j\}, \mathcal{E} = \mathcal{E}_0 \cup \mathcal{E}_1$

$$E_{ii} = \operatorname{diag}(0, \dots, 0, 1_i, 0, \dots, 0)$$

$$E_{ij}^+ \text{ has minor } \begin{pmatrix} 1_{ii} & 1_{ij} \\ 1_{ji} & 1_{jj} \end{pmatrix}, 0 \text{ elsewhere}$$

$$E_{ij}^- \text{ has minor } \begin{pmatrix} 1_{ii} & -1_{ij} \\ -1_{ji} & 1_{jj} \end{pmatrix}, 0 \text{ elsewhere}$$

- ▶ Thm. $\mathbb{DD} = \text{cone generated by } \mathcal{E}_{[Barker & Carlson 1975]}$ Pf. Rays in \mathcal{E} are extreme, all DD matrices generated by \mathcal{E}
- ▶ Cor. DD finitely gen. by $\mathcal{X}_{DD} = \{e_i \mid i \leq n\} \cup \{(e_i \pm e_j) \mid i < j \leq n\}$ Pf. Verify $E_{ii} = e_i e_i^\top$, $E_{ij}^\pm = (e_i \pm e_j)(e_i \pm e_j)^\top$, where e_i is the *i*-th std basis element of \mathbb{R}^n

Finitely generated dual cone representation

Thm. If C finitely gen. by
$$\mathcal{X}$$
, then

$$C^* = \{Y \in \mathbb{S}^n \mid \forall x \in \mathcal{X} \ (Y \bullet xx^\top \ge 0)\}$$
recall $C^* \triangleq \{Y \in \mathbb{S}^n \mid \forall x \in C \mid Y \bullet x \ge 0\}$

 \triangleright (\supset) Let Y s.t. $\forall x \in \mathcal{X} (Y \bullet xx^{\top} > 0)$ $\blacktriangleright \forall X \in C, X = \sum \delta_x x x^{\top}$ (by fin. gen.) $r \in \mathcal{X}$ • hence $Y \bullet X = \sum_{x} \delta_{x} Y \bullet x x^{\top} \ge 0$ (by defn. of Y) • whence $Y \in C^*$ (by define of C^*) $\blacktriangleright (\subseteq) \text{ Suppose } Z \in C^* \smallsetminus \{Y \mid \forall x \in \mathcal{X} (Y \bullet xx^\top > 0)\}$ • then $\exists \mathcal{X}' \subset \mathcal{X}$ s.t. $\forall x \in \mathcal{X}' \ (Z \bullet xx^{\top} < 0)$ • consider any $Y = \sum \delta_x x x^\top \in C$ with $\delta \ge 0$ $x \in \mathcal{X}'$ • then $Z \bullet Y = \sum \delta_x Z \bullet x x^\top < 0$ so $Z \notin C^*$ $r \in \mathcal{X}'$ • contradiction $\Rightarrow C^* = \{Y \mid \forall x \in \mathcal{X} (Y \bullet xx^\top \ge 0)\}$

Dual cone constraints

- **Remark**: for $v \in \mathbb{R}^n$, $X \bullet vv^{\top} = v^{\top}Xv$
- ▶ Use finitely generated dual cone theorem
- \blacktriangleright Decision variable matrix X
- ► Constraints:

 $\forall v \in \mathcal{X} \quad v^{\top} X v \ge 0$

▶ Cor. $DD^* \supset PSD$

Pf. $X \in \mathbb{PSD}$ iff $\forall v \in \mathbb{R}^n \ vXv \ge 0$, so certainly valid $\forall v \in \mathcal{X}$

► If |X| polysized, get compact formulation otherwise use column generation

 $\blacktriangleright |\mathcal{X}_{\mathbb{DD}}| = |\mathcal{E}| = O(n^2)$

Dual cone DDP formulation for DGP

$$\min \left\{ \begin{array}{ll} \min \left\{ X_{ii} + X_{jj} - 2X_{ij} \right\} \\ \{i, j\} \in E \\ \forall v \in \mathcal{X}_{\mathbb{DD}} \end{array} \right\} \left\{ \begin{array}{ll} X_{ii} + X_{jj} - 2X_{ij} \\ v^{\top}Xv \geq 0 \end{array} \right\}$$

• $v^{\top}Xv \ge 0$ for $v \in \mathcal{X}_{\mathbb{DD}}$ equivalent to:

 $\forall i \le n \quad X_{ii} \ge 0$ $\forall \{i, j\} \notin E \quad X_{ii} + X_{jj} - 2X_{ij} \ge 0$ $\forall i < j \quad X_{ii} + X_{jj} + 2X_{ij} \ge 0$

Note we went back to equality "pull" constraints (why?)

Quantifier $\forall \{i,j\} \not\in E$ should be $\forall i < j$ but we already have those constraints $\forall \{i,j\} \in E$

Properties

- ▶ SDP relaxes original problem
- DualDDP relaxes SDP hence also relaxes original problem
- ▶ Yields tight obj fun bounds w.r.t. SDP
- Solutions may have large negative rank in some applications, retrieving feasible solutions may be difficult

Project idea 3: Apply the DG methods seen in these lectures in order to control a fleet of submarine robots (for each time instant $t \in T$ they define a different distance graph)

Subsection 8

Barvinok's Naive Algorithm

Concentration of measure

From [Barvinok, 1997]

The value of a "well behaved" function at a random point of a "big" probability space X is "very close" to the mean value of the function.

and

In a sense, measure concentration can be considered as an extension of the law of large numbers.

Concentration of measure

Given Lipschitz function $f: X \to \mathbb{R}$ s.t.

$$\forall x, y \in X \quad |f(x) - f(y)| \le L ||x - y||_2$$

for some $L \ge 0$, there is *concentration of measure* if \exists constants c, C s.t.

$$\forall \varepsilon > 0 \quad \mathsf{P}_x(|f(x) - \mathsf{E}(f)| > \varepsilon) \le c \, e^{-C\varepsilon^2/L^2}$$

where $\mathsf{E}(\cdot)$ is w.r.t. given Borel measure μ over X

\equiv "discrepancy from mean is unlikely"

Barvinok's theorem

Consider:

- ▶ for each $k \leq m$, manifolds $\mathcal{X}_k = \{x \in \mathbb{R}^n \mid x^\top Q^k x = a_k\}$ where $m \leq \operatorname{poly}(n)$
- feasibility problem $F \equiv \left[\bigcap_{k \leq m} \mathcal{X}_k \neq \varnothing\right]$
- ▶ SDP relaxation $\forall k \leq m (Q^k \bullet X = a_k) \land X \succeq 0$ with soln. \bar{X}
- ► Algorithm: $T \leftarrow \mathsf{factor}(\bar{X}); \quad y \sim \mathsf{N}^n(0,1); \quad x' \leftarrow Ty$

Then:

▶
$$\exists c > 0, n_0 \in \mathbb{N}$$
 such that $\forall n \ge n_0$

$$\mathsf{Prob}\left(\forall k \le m \quad \mathsf{dist}(x', \mathcal{X}_k) \le c \sqrt{\|\bar{X}\|_2 \ln n}\right) \ge 0.9.$$

Algorithmic application

- x' is "close" to each \mathcal{X}_k : try local descent from x'
- $\blacktriangleright \Rightarrow$ Feasible QP solution from an SDP relaxation

Elements of Barvinok's formula

$$\mathsf{Prob}\left(\forall k \le m \quad \mathsf{dist}(x', \mathcal{X}_k) \le c \sqrt{\|\bar{X}\|_2 \ln n}\right) \ge 0.9.$$

- $\sqrt{\|\bar{X}\|_2}$ arises from T (a factor of \bar{X})
- $\sqrt{\ln n}$ arises from concentration of measure
- ▶ 0.9 follows by adjusting parameter values in "union bound"

Application to the DGP

$$\blacktriangleright \quad \forall \{i, j\} \in E \quad \mathcal{X}_{ij} = \{x \mid ||x_i - x_j||_2^2 = d_{ij}^2\}$$

• DGP can be written as
$$\bigcap_{\{i,j\}\in E} \mathcal{X}_{ij} \stackrel{?}{\neq} \varnothing$$

- SDP relaxation $X_{ii} + X_{jj} 2X_{ij} = d_{ij}^2 \wedge X \succeq 0$ with soln. \overline{X}
- ▶ Difference with Barvinok: $x \in \mathbb{R}^{Kn}$, $\operatorname{rk}(\bar{X}) \leq K$
- ► IDEA: sample $y \sim \mathsf{N}^{nK}(0, \frac{1}{\sqrt{K}})$
- ▶ Thm. Barvinok's theorem works in rank K

Proof structure

▶ Show that, on average, $\forall k \leq m \operatorname{tr}((Ty)^{\top}Q^{k}(Ty)) = Q^{k} \bullet \overline{X} = a_{k}$

compute multivariate integrals

 \blacktriangleright bilinear terms disappear because y normally distributed

• decompose multivariate int. to a sum of univariate int.

▶ Exploit concentration of measure to show errors happen rarely

▶ a couple of technical lemmata yielding bounds

▶ ⇒ bound Gaussian measure μ of ε -neighbourhoods of

$$\begin{aligned} A_i^- &= \{ y \in \mathbb{R}^{n \times K} \mid \mathcal{Q}^i(Ty) \le Q^i \bullet \bar{X} \} \\ A_i^+ &= \{ y \in \mathbb{R}^{n \times K} \mid \mathcal{Q}^i(Ty) \ge Q^i \bullet \bar{X} \} \\ A_i &= \{ y \in \mathbb{R}^{n \times K} \mid \mathcal{Q}^i(Ty) = Q^i \bullet \bar{X} \}. \end{aligned}$$

use "union bound" for measure of A⁻_i(ε) ∩ A⁺_i(ε)
show A⁻_i(ε) ∩ A⁺_i(ε) = A_i(ε)
use "union bound" to measure intersections of A_i(ε)
appropriate values for some parameters ⇒ result

The heuristic

1. Solve SDP relaxation of DGP, get soln. \bar{X} use DDP+LP if SDP+IPM too slow

2. a.
$$T = \text{factor}(\bar{X})$$

b. $y \sim N^{nK}(0, \frac{1}{\sqrt{K}})$
c. $x' = Ty$

3. Use x' as starting point for a local NLP solver on formulation

$$\min_{x} \sum_{\{i,j\} \in E} \left(\|x_i - x_j\|^2 - d_{ij}^2 \right)^2$$

and return improved solution x

Subsection 9

Isomap revisited

Isomap for the DGP

• Given DGP instance (K, G = (V, E, d)):

- 1. D = square weighted adjacency matrix of G
- 2. \overline{D} = completion of D

3.
$$x' = \text{PCA}(\bar{D}, K)$$

4. x =locally optimal solution closest to x

Step 4 is the "refinement step" calls a local solver for the DGP with starting point x'

▶ Vary Step 2 to generate Isomap-based heuristics

Variants for Step 2

- A. Floyd-Warshall all-shortest-paths algorithm on G (classic Isomap)
- B. Find a spanning tree (SPT) of G and compute a random realization in $\bar{x} \in \mathbb{R}^{K}$, use its sqEDM
- C. Solve a push-and-pull SDP/DDP/DualDDP to find a realization $x' \in \mathbb{R}^n,$ use its sqEDM

Project idea 4: implement and test at least 6 different variants of Isomap for DGP: the three above, and at least three new ones of your own conception

Subsection 10

Summary

Matrix reformulations

- Quadratic nonconvex too difficult?
- ► Solve SDP relaxation
- ▶ SDP relaxation too large?
- ► Solve DDP approximation
- Get $n \times n$ matrix solution, need $K \times n!$

Solution rank reduction methods

- ▶ Multidimensional Scaling (MDS)
- Principal Component Analysis (PCA)
- ▶ Barvinok's naive algorithm (BNA)
- ► Isomap

All provide good starting points for local solvers

Can also use them for general dimensionality reduction: they map n vectors in $\mathbb{R}^n \longrightarrow n$ vectors in \mathbb{R}^K

Outline

Introduction

Summary

Random projections in LP

Random projection theory Projecting LP feasibility Projecting LP optimality Solution retrieval Application to quantile regression

Sparsity and ℓ_1 minimization

Motivation Basis pursuit Theoretical results Application to noisy channel encoding Improvements

Kissing Number Problem

Lower bounds Upper bounds from SDP? Gregory's upper bound Delsarte's upper bound Pfender's upper bound

Clustering in Natural Language

Clustering on graphs Clustering in Euclidean spaces Distance instability MP formulations Random projections again The gist of random projections (RP)

▶ Let A be a m × n data matrix (columns in ℝ^m, m ≫ 1)
▶ T short & fat, normally sampled componentwise

▶ Then $\forall i < j ||A_i - A_j||_2 \approx ||TA_i - TA_j||_2$ "wahp"

wahp

"wahp" = "with arbitrarily high probability" the probability of E_k (depending on some parameter k) approaches 1 "exponentially fast" as k increases

$$\mathbf{P}(E_k) \ge 1 - O(e^{-k})$$

Johnson-Lindenstrauss Lemma (JLL)

Thm.

Given $A \subseteq \mathbb{R}^m$ with |A| = n and $\varepsilon > 0$ there is $k = O(\frac{1}{\varepsilon^2} \ln n)$ and a $k \times m$ matrix T s.t.

 $\forall x, y \in A \quad (1 - \varepsilon) \|x - y\| \leq \|Tx - Ty\| \leq (1 + \varepsilon) \|x - y\|$

If $k \times m$ matrix T is sampled componentwise from $N(0, \frac{1}{\sqrt{k}})$, then $\mathbf{P}(A \text{ and } TA \text{ approximately congruent}) \geq \frac{1}{n}$ (nontrivial) — result follows by probabilistic method

Note that $1/\sqrt{k}$ is the standard deviation, not the variance

In practice

- ▶ $\mathbf{P}(A \text{ and } TA \text{ approximately congruent}) \geq \frac{1}{n}$
- ▶ re-sampling sufficiently many times gives wahp
- Empirically, sample T few times (once will do) $\mathbb{E}_T(||Tx - Ty||) = ||x - y||$ probability of error decreases wahp

Surprising fact:

k is independent of the original number of dimensions \boldsymbol{m}

Clustering Google images

[L. & Lavor, 2017]
Clustering without RPs

VHcl = Timing[ClusteringComponents[VHimg, 3, 1]]
Out[29]= {0.405908, {1, 2, 2, 2, 2, 2, 3, 2, 2, 3}}

Too slow!

Clustering with RPs

Get["Projection.m"]; VKimg = JohnsonLindenstrauss[VHimg, 0.1]; VKcl = Timing[ClusteringComponents[VKimg, 3, 1]] Out[34]= {0.002232, {1, 2, 2, 2, 2, 2, 3, 2, 2, 2, 3}}

> From 0.405s CPU time to 0.00232s Same clustering

Projecting formulations

► Given:

- F(p, x): MP formulation with params p & vars x
- ▶ sol(F): solution of F
- ▶ C: formulation class (e.g. LP, NLP, MILP, MINLP)
- Given RP T, define T F(p, x) as F(Tp, x) or F(Tp, Tx)
- ▶ Want to show: $\forall F \in \mathscr{C} \operatorname{sol}(F) \approx \operatorname{sol}(TF)$ wahp
- ► Issues:
 - RPs project points not vars/constrs
 - approximate congruence \neq feasibility/optimality
 - JLL applies to finite pt sets, vars encode ∞ pts
- ▶ Today we see this for $\mathscr{C} = LP$
- ▶ Can also be applied to QP, SDP, QCQP, and more

Subsection 1

Random projection theory

The shape of a set of points

► Lose dimensions but not too much accuracy Given $A_1, ..., A_n \in \mathbb{R}^m$ find $k \ll m$ and $A'_1, ..., A'_n \in \mathbb{R}^k$ s.t. A and A' "have almost the same shape"

What is the shape of a set of points?

congruence \Leftrightarrow same shape: $\|A_i - A_j\| = \|A'_i - A'_j\|$

• Approximate congruence \equiv small distortion: A, A' have almost the same shape if $\forall i < j \leq n \quad (1-\varepsilon) \|A_i - A_j\| \leq \|A'_i - A'_j\| \leq (1+\varepsilon) \|A_i - A_j\|$ for some small $\varepsilon > 0$

Assume norms are all Euclidean

Losing dimensions = "projection"

In the plane, hopeless

In 3D: no better

Recall the JLL

Thm.

Given $A \subseteq \mathbb{R}^m$ with |A| = n and $\varepsilon > 0$ there is $k = O(\frac{1}{\varepsilon^2} \ln n)$ and a $k \times m$ matrix T s.t.

 $\forall x, y \in A \quad (1 - \varepsilon) \|x - y\| \leq \|Tx - Ty\| \leq (1 + \varepsilon) \|x - y\|$

Approximate congruence: proof sketch

RPs preserve norms on average

Thm.
Let T be a
$$k \times m$$
 rectangular matrix with each component sampled from
 $N(0, \frac{1}{\sqrt{k}})$, and $u \in \mathbb{R}^m$ s.t. $||u|| = 1$. Then $\mathbb{E}(||Tu||^2) = 1$
Proof
Let $v = Tu$, i.e. $\forall i \le k$ let $v_i = \sum_{j \le n} T_{ij}u_j$
 $\mathbb{E}(v_i) = \mathbb{E}\left(\sum_{j \le m} T_{ij}u_j\right) = \sum_{j \le m} \mathbb{E}(T_{ij})u_j = 0$
 $\mathbb{Var}(v_i) = \sum_{j \le m} \operatorname{Var}(T_{ij}u_j) = \sum_{j \le m} \operatorname{Var}(T_{ij})u_j^2 = \sum_{j \le m} \frac{u_j^2}{k} = \frac{1}{k}||u||^2 = \frac{1}{k}$
 $\frac{1}{k} = \operatorname{Var}(v_i) = \mathbb{E}(v_i^2 - (\mathbb{E}(v_i))^2) = \mathbb{E}(v_i^2 - 0) = \mathbb{E}(v_i^2)$
 $\mathbb{E}(||Tu||^2) = \mathbb{E}(||v||^2) = \mathbb{E}\left(\sum_{i \le k} v_i^2\right) = \sum_{i \le k} \mathbb{E}(v_i^2) = \sum_{i \le k} \frac{1}{k} = 1$

Can we argue that the variance decreases wahp?

Surface area of a slice of hypersphere $\bar{S}_m(r)$: surface of *m*-dimensional sphere of radius *r*

$$\bar{S}_m(r) = \frac{2\pi^{m/2}r^{m-1}}{\Gamma(m/2)} \qquad S_m \triangleq \bar{S}_m(1)$$

Lateral surface of infinitesimally high hypercylinder

$$d\bar{S}_m(\sqrt{1-t^2}) = S_{m-1}(1-t^2)^{\frac{m-2}{2}}dt$$

Area of polar caps

$$\mathcal{A}^{\rm pc} = 2\int_t^1 d\bar{S}_m(s) = 2S_{m-1}\int_t^1 (1-s^2)^{\frac{m-2}{2}} ds$$

 $1 + x \le e^x$ for all x and $\int_t^1 f(s)ds \le \int_t^\infty f(s)ds$ for $f \ge 0$

$$\Rightarrow \mathcal{A}^{\mathrm{pc}} \leq 2S_{m-1} \int_{t}^{\infty} e^{-\frac{m-2}{2}s^2} ds = \frac{2S_{m-1}}{\sqrt{m-2}} \sqrt{\frac{\pi}{2}} \operatorname{erfc}\left(\frac{\sqrt{m-2}t}{\sqrt{2}}\right) \stackrel{\text{``}}{\approx} \stackrel{\text{''}}{O}(e^{-t^2})$$

- ▶ Polar caps area decreases as $m \to \infty$ with t fixed
- Concentration of measure of the equatorial band

An intuitive explanation

- ▶ Polar caps area $\mu(\mathcal{A}_t^m) = \mu(\{u \in \mathbb{S}^{m-1} \mid |u_m| > t\})$ decreases with t fixed as $m \to \infty \Rightarrow$ area of equatorial band $\overline{\mathcal{A}}_t^m$ increases with same conditions
- ▶ $T\bar{\mathcal{A}}_t^m = \{u \in \mathbb{S}^{m-1} \mid |||Tu||^2 1| \leq t\}$ has concentration of

measure (if T is stereographic)

Intermezzo: The union bound

• Events E_1, \ldots, E_k such that $\mathbf{P}(E_i) \ge 1 - p$ for each $i \le k$

• What is $\mathbf{P}(\text{all } E_i)$?

▶
$$\mathbf{P}(\text{all } E_i) = 1 - \mathbf{P}(\text{at least one } \neg E_i) \Rightarrow$$

$$\mathbf{P}\left(\bigwedge_{i\leq k} E_i\right) = 1 - \mathbf{P}\left(\bigvee_{i\leq k} (\neg E_i)\right) \ge$$
$$\ge 1 - \sum_{i=1}^k \mathbf{P}(\neg E_i) \ge 1 - \sum_{i=1}^k (1 - (1 - p)) = 1 - kp$$

► So $\mathbf{P}(\text{all } E_i) \ge 1 - kp$

A syntactical explanation for $k = O(\varepsilon^{-2} \ln n)$

- ► B = set of unit vectors; by "intuitive explanation" $\Rightarrow \forall u \in B \exists C > 0 \text{ s.t. } \mathbf{P}(1 - t \leq ||Tu|| \leq 1 + t) \geq 1 - e^{-Ct^2}$
- ► By union bound: $\Rightarrow \mathbf{P}(\forall u \in B \ 1 - t \le ||Tu|| \le 1 + t) \ge 1 - |B|e^{-Ct^2}$

▶ Prob.
$$\in [0, 1] \Rightarrow$$
 require $1 - |B|e^{-Ct^2} > 0$:
 $\Rightarrow |B|e^{-Ct^2} < 1$

• (arbitrarily) Let $t = \varepsilon \sqrt{k}$: $\Rightarrow |B|e^{-C\varepsilon^2 k} < 1$

 $\blacktriangleright \Rightarrow k > C\varepsilon^{-2}\ln(|B|)$

Apply to vector differences

- Let $A \subset \mathbb{R}^m$, |A| = n
- $\blacktriangleright \quad \forall x, y \in A \text{ we have}$

$$||Tx - Ty||^{2} = ||T(x - y)||^{2} = ||x - y||^{2} \left||T\frac{x - y}{||x - y||}\right|^{2} = ||x - y||^{2} ||Tu||^{2}$$

where $||u||_{2} = 1$

•
$$\mathbb{E}(||Tu||^2) = ||u|| = 1 \Rightarrow \mathbb{E}(||Tx - Ty||^2) = ||x - y||^2$$

► Let
$$B = \{\frac{x-y}{\|x-y\|} \mid x, y \in A\}$$

 $|B| = O(n^2) \Rightarrow k = C\varepsilon^{-2}\ln(n)$ for some constant C

▶ By concentration of measure on $T\bar{\mathcal{A}}^m$, $\exists \varepsilon \in (0,1)$ s.t.

$$(1-\varepsilon)\|x-y\|^2 \le \|Tx-Ty\|^2 \le (1+\varepsilon)\|x-y\|^2$$
 (*)

holds with positive probability

▶ Probabilistic method: ∃T such that (*) holds ⇒ JLL follows

Randomized algorithm

Distortion has low probability [Gupta 02]:

 $\begin{aligned} \forall x, y \in A \quad \mathbf{P}(\|Tx - Ty\| \le (1 - \varepsilon)\|x - y\|) &\le 1/n^2 \\ \forall x, y \in A \quad \mathbf{P}(\|Tx - Ty\| \ge (1 + \varepsilon)\|x - y\|) &\le 1/n^2 \end{aligned}$

▶ Probability \exists pair $x, y \in A$ distorting Euclidean distance: union bound over $\binom{n}{2}$ pairs

 $\mathbf{P}(\neg(A \text{ and } TA \text{ have almost the same shape})) \leq \binom{n}{2} \frac{2}{n^2} = 1 - \frac{1}{n}$ $\mathbf{P}(A \text{ and } TA \text{ have almost the same shape}) \geq 1/n$

► Algorithm:

- ▶ $\mathbf{P}(\exists x, y \in A \text{ with large JLL discrepancy}) \leq 1 1/n$
- Consider t > 1 independent samplings of random RP T
- ▶ Probability that all have large discrepancy: $\leq (1 1/n)^t$
- Choose t so at least one T will be good with prob. ≥ 0.99 : $(1 - 1/n)^t \le 1 - 0.99 = 0.01$ yields $t \ge \ln(0.01)/\ln(1 - 1/n)$ if n = 100, get $t \ge 459$

Subsection 2

Projecting LP feasibility

Pure feasibility LP: easy cases

Thm.

 $T: \mathbb{R}^m \to \mathbb{R}^k$ a RP, and $b, A_1, \dots, A_n \in \mathbb{R}^m$. For any given vector $x \in X$, we have:

(i) If
$$b = \sum_{i=1}^{n} x_i A_i$$
 then $Tb = \sum_{i=1}^{n} x_i TA_i$
by linearity of T
(ii) If $b \neq \sum_{i=1}^{n} x_i A_i$ then $\mathbf{P}\left(Tb \neq \sum_{i=1}^{n} x_i TA_i\right) \ge 1 - 2e^{-Ck}$
by JLL applied to $||b - \sum_i x_i A_i||$
(iii) If $b \neq \sum_{i=1}^{n} y_i A_i$ for all $y \in X \subseteq \mathbb{R}^n$, where $|X|$ is finite, then
 $\mathbf{P}\left(\forall y \in X \ Tb \neq \sum_{i=1}^{n} y_i TA_i\right) \ge 1 - 2|X|e^{-Ck}$
for some constant $C > 0$ (independent of n, k)
by union bound

[Vu et al., Math of OR, 2018]

Separating hyperplanes

When |X| is large, project separating hyperplanes instead

- ► Convex $C \subseteq \mathbb{R}^m$, $x \notin C$: then \exists hyperplane c separating x from C
- ▶ In particular, true if $C = \operatorname{cone}(A_1, \ldots, A_n)$ for $A \subseteq \mathbb{R}^m$
- Can show $x \in C \Leftrightarrow Tx \in TC$ with high probability
- As above, if $x \in C$ then $Tx \in TC$ by linearity of T Difficult part is proving the converse
- Can also project point-to-cone distances

Projection of separating hyperplanes

Thm.

Given $c, b, A_1, \ldots, A_n \in \mathbb{R}^m$ of unit norm s.t. $b \notin \operatorname{cone}\{A_1, \ldots, A_n\}$ pointed, $\varepsilon > 0$, $c \in \mathbb{R}^m$ s.t. $c^\top b < -\varepsilon$, $c^\top A_i \ge \varepsilon$ $(i \le n)$, and T a RP:

$$\mathbf{P}[Tb \notin \mathsf{cone}\{TA_1, \dots, TA_n\}] \ge 1 - 4(n+1)e^{-\mathcal{C}(\varepsilon^2 - \varepsilon^3)k}$$

for some constant C.

Proof

Let \mathscr{A} be the event that T approximately preserves $||c - \chi||^2$ and $||c + \chi||^2$ for all $\chi \in \{b, A_1, \ldots, A_n\}$. Since \mathscr{A} consists of 2(n + 1) events, by the JLL ("squared variant") and the union bound, we get

$$\mathbf{P}(\mathscr{A}) \ge 1 - 4(n+1)e^{-\mathcal{C}(\varepsilon^2 - \varepsilon^3)k}$$

Now consider $\chi = b$

$$\langle Tc, Tb \rangle = \frac{1}{4} (\|T(c+b)\|^2 - \|T(c-b)\|^2)$$

by JLL $\leq \frac{1}{4} (\|c+b\|^2 - \|c-b\|^2) + \frac{\varepsilon}{4} (\|c+b\|^2 + \|c-b\|^2)$
 $= c^\top b + \varepsilon < 0$

and similarly $\langle Tc, TA_i \rangle \geq 0$

[Vu et al., Math. OR, 2018]

The feasibility projection theorem

Thm. Given $\delta > 0$, \exists sufficiently large $m \le n$ such that: for any LFP input A, b where A is $m \times n$ we can sample a random $k \times m$ matrix T with $k \ll m$ and

P(orig. LFP feasible \iff proj. LFP feasible) $\geq 1 - \delta$

Subsection 3

Projecting LP optimality

Notation

- $P \equiv \min\{cx \mid Ax = b \land x \ge 0\}$ (original problem)
- $\blacktriangleright TP \equiv \min\{cx \mid TAx = Tb \land x \ge 0\} (projected \ problem)$
- ▶ v(P) = optimal objective function value of P
- v(TP) = optimal objective function value of TP

The optimality projection theorem

Assume feas(P) is bounded
 Assume all optima of P satisfy Σ_j x_j ≤ θ for some given θ > 0

(prevents unboundedness)

<u>Thm.</u>

Given $\gamma > 0$,

$$v(\mathbf{P}) - \gamma \le v(TP) \le v(\mathbf{P}) \qquad (*)$$

holds with arbitrarily high probability (w.a.h.p.)

more precisely, (*) holds with prob. $1 - 4ne^{-\mathcal{C}(\varepsilon^2 - \varepsilon^3)k}$ where $\varepsilon = \gamma/(2(\theta + 1)\eta)$ and $\eta = O(||y||_2)$ where y is a dual optimal solution of **P** having minimum norm

The easy part

Show $v(TP) \leq v(P)$:

- Constraints of $P: Ax = b \land x \ge 0$
- Constraints of TP: $TAx = Tb \land x \ge 0$
- ▶ \Rightarrow constraints of *TP* are lin. comb. of constraints of *P*
- ▶ \Rightarrow any solution of *P* is feasible in *TP* (btw, the converse holds almost never)
- \triangleright *P* and *TP* have the same objective function

▶ ⇒ TP is a relaxation of P ⇒ $v(TP) \le v(P)$

The hard part (sketch)

• Eq. (12) equivalent to P for $\gamma = 0$

$$\begin{array}{rcl}
cx &\leq & v(P) - \gamma \\
Ax &= & b \\
x &\geq & 0
\end{array}$$

(12)

Note: for $\gamma > 0$, Eq. (12) is infeasible

▶ By feasibility projection theorem,

$$\left.\begin{array}{ccc} cx & \leq & v(P) - \gamma \\ TAx & = & Tb \\ x & \geq & 0 \end{array}\right\}$$

is infeasible w.a.h.p. for $\gamma>0$

- ► Re-state: $cx < v(P) \gamma \wedge TAx = Tb \wedge x \ge 0$ infeasible w.a.h.p.
- ► $\Rightarrow cx \ge v(P) \gamma$ holds w.a.h.p. for $x \in \mathsf{feas}(TP)$

$$\blacktriangleright \Rightarrow v(P) - \gamma \le v(TP)$$

Subsection 4

Solution retrieval

Projected solutions are infeasible in P

$$\blacktriangleright Ax = b \Rightarrow TAx = Tb$$
by linearity

However, Thm. For $x \ge 0$ s.t. TAx = Tb, Ax = b with probability zero

if not, an x belonging to (n-k)-dim. subspace would belong to an (n-m)-dim. subspace (with $k \ll m$) with positive probability

Can't get solution for original LFP using projected LFP!

Solution retrieval by duality

▶ Primal min{
$$c^{\top}x \mid Ax = b \land x \ge 0$$
} ⇒ dual max{ $b^{\top}y \mid A^{\top}y \le c$ }

• Let
$$x' = \operatorname{sol}(TP)$$
 and $y' = \operatorname{sol}(\operatorname{dual}(TP))$

$$\blacktriangleright \Rightarrow (TA)^{\top} y' = (A^{\top} T^{\top}) y' = A^{\top} (T^{\top} y') \le c$$

► ⇒
$$T^{\top}y'$$
 is a solution of $\mathsf{dual}(P)$

- ▶ ⇒ we can compute an optimal basis J for P
- Solve $A_J x_J = b$, get x_J , obtain a solution x^* of P
- ▶ Won't work in practice: errors in computing J

Solution retrieval by projected basis

- H: optimal basis of TP we can trust that — given by solver
- $\blacktriangleright |H| = k \Rightarrow A_H \text{ is } m \times k \text{ (tall and slim)}$
- ► Pseudoinverse: solve $k \times k$ system $A_H^{\top} A_H x_H = A_H^{\top} b$ $\Rightarrow x_H = (A_H^{\top} A_H)^{-1} A_H^{\top} b$

$$\blacktriangleright \quad \text{let } x = (x_H, 0)$$

- ► Can prove small feasibility error wahp
- ▶ **ISSUE**: may be slightly infeasible empirically: $x \ge 0$ but $x^- = \min(0, x) \to 0$ as $k \to \infty$

Project idea 5: Test the output of duality and projected basis retrieval methods on a set of 50 random large feasible standard-form LPs: you should find that the duality method is worse than the projected basis method. Formulate a reasoned hypothesis about the reason why this happens

Projected LP duals

- The dual of $P \equiv \min\{cx \mid Ax = b \land x \ge 0\}$ is $D \equiv \max\{yb \mid yA \le c\}$
- ► A projected dual on $y \in \mathbb{R}^m$ can be derived as follows: $\max\{(yT^{\top})Tb \mid (yT^{\top})TA \leq c\}$
- ▶ Replacing $u = yT^{\top} \in \mathbb{R}^k$, we obtain $TD \equiv \max\{u\bar{b} \mid u\bar{A} \leq c\}$ where $\bar{b} = Tb$, $\bar{A} = TA$
- ▶ Theory [D'Ambrosio et al. MPB 2020]:
 - if original dual is feasible, projected dual is feasible
 approximation guarantees on projected dual objective function
 retrieval: if ū ∈ arg opt(TD), let ỹ = ūT, ỹ is feasible in D

Project idea 6: Develop an algorithm for finding a candidate solution x' of P from \tilde{y} . Sample 50 random large standard form LP instances, solve P, TP, TD for each instance. Collect soln. x^* from P, \tilde{x} from TP, x' from TD, then compute objective function value and feasibility error w.r.t. P of x^*, \tilde{x}, x' . Plot all this data in function of the number of rows of A and ε

Subsection 5

Application to quantile regression

Conditional random variables

▶ random variable *B* conditional on A_1, \ldots, A_p

▶ assume *B* depends linearly on $\{A_j \mid j \leq p\}$

• want to find $x_1, \ldots, x_n \in \mathbb{R}$ s.t.

$$B = \sum_{j \le p} x_j A_j$$

• use samples $b, a_1, \ldots, a_p \in \mathbb{R}^m$ to find estimates

$$\blacktriangleright a^i = \text{row}, a_j = \text{column}$$

Sample statistics

► expectation:

$$\hat{\mu} = \arg\min_{\mu \in \mathbb{R}} \sum_{i \le m} (b_i - \mu)^2$$

► conditional expectation (*linear regression*):

$$\hat{\nu} = \operatorname*{arg\,min}_{\nu \in \mathbb{R}^p} \sum_{i \leq m} (b_i - \underbrace{\nu a^i})^2$$

▶ sample median:

$$\begin{split} \hat{\xi} &= \arg\min_{\xi \in \mathbb{R}} \sum_{i \le m} |b_i - \xi| \\ &= \arg\min_{\xi \in \mathbb{R}} \sum_{i \le m} \left(\frac{1}{2} \max(b_i - \xi, 0) - \frac{1}{2} \min(b_i - \xi, 0) \right) \end{split}$$

► conditional sample median: *similarly*

Quantile regression

▶ sample τ -quantile:

$$\hat{\xi} = \arg\min_{\xi \in \mathbb{R}} \sum_{i \le m} \left(\tau \max(b_i - \xi, 0) - (1 - \tau) \min(b_i - \xi, 0) \right)$$

• conditional sample τ -quantile (quantile regression):

$$\hat{\beta} = \arg\min_{\beta \in \mathbb{R}^p} \sum_{i \le m} \left(\tau \max(b_i - \beta a^i, 0) - (1 - \tau) \min(b_i - \beta a^i, 0) \right)$$

Linear Programming formulation

Let $A = (a_j \mid j \leq n)$; then

$$\hat{\beta} = \arg\min \left\{ \begin{array}{ccc} \tau u^{+} + (1 - \tau)u^{-} \\ A(\beta^{+} - \beta^{-}) + u^{+} - u^{-} &= b \\ \beta, u &\geq 0 \end{array} \right\}$$

> parameters: A is $m \times p, b \in \mathbb{R}^m, \tau \in \mathbb{R}$

- ▶ decision variables: $\beta^+, \beta^- \in \mathbb{R}^p, u^+, u^- \in \mathbb{R}^m$
- ▶ LP constraint matrix is $m \times (2p + 2m)$ density: p/(p+m) — can be high

Project idea 7: Test the application of RPs on at least 50 large random MULTICOMMODITY FLOW (MCF) problems. Plot the ratio of projected to original objective, retrieved to original objective, and infeasibility errors in function of the number of rows of the equality system Ax = b and ε . Is MCF a good application testbed for RP?
Large datasets

Russia Longitudinal Monitoring Survey hh1995f

- harphi m = 3783, p = 855
- $\blacktriangleright A = \texttt{hf1995f}, \ b = \log \operatorname{avg}(A)$
- 18.5% dense
- poorly scaled data, CPLEX yields infeasible (!!!) after around 70s
 CPU
- quantreg in R fails

▶ 14596 RGB photos on my HD, scaled to 90×90 pixels

- each row of A is an image vector, $b = \sum A$
- 62.4% dense
- CPLEX killed by OS after ≈30min (presumably for lack of RAM) on 16GB
- could not load dataset in R

Electricity prices

- Every hour over 365 days in 2015 (8760 rows)
- ▶ From 22 countries (columns) from the European zone

Subsection 1

Motivation

Coding problem for costly channels

 \blacktriangleright Task:

send long sparse vector $y \in \mathbb{R}^n$ on costly channel

- 1. construct $m \times n$ encoding matrix A with $m \le n$ both parties know A
- 2. encode $b = Ay \in \mathbb{R}^m$ (shorter than y)

3. send b (spend less than by sending y)

► Decode by finding sparsest x s.t. Ax = bcan we expect $x \approx y$, i.e. small ||x - y||?

► Summary:

- 1. given long sparse vector y
- 2. shorten it to b, send b
- 3. upon receiveing b, recover long sparse vector $x \approx y$

Coding problem for noisy channels

- <u>Task</u>: send vector $w \in \mathbb{R}^d$ on a noisy channel
- Encoding: $n \times d$ matrix Q with n > d, send $z = Qw \in \mathbb{R}^n$ z longer than w for redundancy both parties know Q
- Error prob. e: en components of z sent wrong
- Receive (wrong) vector $\overline{z} = z + x$ where x is sparse
- Can we recover z?

n-d

Q

AQ= O

- Choose $m \times n$ matrix A s.t. m = n d and AQ = 0
- Let $b = A\overline{z} = A(z+x) = A(Qw+x) = AQw + Ax = Ax$
- Suppose we can find sparsest x' s.t. Ax' = b

$$\blacktriangleright \Rightarrow \text{we can recover } z' = \bar{z} - x'$$

► Recover $w' = (Q^{\top}Q)^{-1}Q^{\top}z'$ (pseudoinverse) What is the likelihood of getting small ||w - w'||?

<u>Summary</u>: 1. given short dense vector w, 2. lengthen it to z for redundancy; 3. send z and receive $\overline{z} = z + x$; 4. find long sparse error vector x using short vector $b = A\overline{z}$; 5. recover z' then w'

What these tasks have in common

- Given matrix A with fewer rows than columns
- \blacktriangleright Given vector b
- Find sparsest solution x^* of Ax = b

• Note: Ax = b feasible iff rank(A) = rank(A|b)

Subsection 2

Basis pursuit

Sparsest solution of a linear system

Problem $P^0(A, b) \equiv \min\{ x _0 \mid Ax = b\}$ is NP-hard Reduction from EXACT COVER BY 3-SETS [Garey&Johnson 1979, A6[MP5]] MILP: $\min\{\sum_j y_j \mid \forall j - My_j \le x_j \le My_j \land Ax = b \land y \in \{0, 1\}^n\}$
$P^{1}(A,b) \equiv \min\{\ x\ _{1} \mid Ax = b\}$
is a relaxation
Reformulate to LP:
min $\sum s_j$
$ \forall j \le n -s_j \le x_j \le s_j \ \ \left\{ \begin{array}{cc} & j \le n \\ (\dagger) \end{array} \right. $
Ax = b
Empirical observation: P^1 often finds optimum of P^0
Too often for this to be a coincidence
Theoretical justification by Candès, Tao, Donoho
Mathematics of sparsity, Compressed sensing, Compressive sampling

▶ Note: we always assume $b \neq 0$ in $P^0(A, b)$ and $P^1(A, b)$

Graphical intuition

• Wouldn't work with ℓ_2, ℓ_∞ norms Ax = b flat at poles — "zero probability of sparse solution"

Warning: this is not a proof, and \exists cases not explained by this drawing [Candès 2014]

Phase transition in sparse recovery For $x \in \mathbb{R}^n$, $A \in \mathbb{R}^{m \times n}$: consider $P^1(A, Ax)$ and its opt. x^*

 $\mathsf{Prob}(x^* \text{ has sparsity } s)$ undergoes a phase transition For a given *n*, if *m* is too small P^1 fails to find the optimum of P^0

[Tropp et al., Information and Inference, 2014]

Subsection 3

Theoretical results

Main theorem and proof structure

Defn. (i) Given a small $\epsilon \ge 0$, a scalar α is *near-zero* if $|\alpha| < \epsilon$; (ii) a vector is *s*-sparse if it has $\le s$ nonzero components

▶ Thm. Let:

- 1. $A \sim \mathsf{N}(0, 1)^{mn}$ with m < n but m "not too small"
- 2. $\hat{x} \in \mathbb{R}^n$ have s nonzeros and n-s zeros or near-zeros
- 3. \bar{x} be the best approx of \hat{x} with exactly s nonzeros
- 4. $\hat{b} = A\hat{x}$ and x^* be the unique s-sparse min of $P^1(A, \hat{b})$

then x^* is a "good approximation" of \bar{x} (*)

► Proof sketch:

- ▶ **Prop.** A has the null space property (NSP) \Rightarrow (*)
- **Prop.** A has restricted isometry prop. (RIP) \Rightarrow A has NSP
- ▶ **Prop.** $A \sim \mathsf{N}(0,1)^{mn} \Rightarrow A$ has RIP
- ▶ adapt to near-zeros by modifying NSP

Some notation

Defn. (i) For any $n \in \mathbb{N}$ define $[n] = \{1, \ldots, n\}$; (ii) for $z \in \mathbb{R}^n$ and $S \subseteq [n]$ let $z[S] = ((z_j \text{ iff } j \in S) \text{ xor } 0 \mid j \leq n)$ be the *restriction* of z to S

- Consider Ax = b where A is m × n with m < n
 if feasible it has uncountably many solutions
- ► Let $x \in \mathbb{R}^n$ s.t. Ax = b, $N_A = \operatorname{null}(A)$, $N_A^0 = N_A \setminus \{0\}$ $\Rightarrow \forall y \in N_A$ we have A(x + y) = Ax + Ay = Ax + 0 = b
- ▶ For $S \subseteq [n]$ let $\overline{S} = [n] \smallsetminus S$
- Note that $\forall z \in \mathbb{R}^n$ we have $z = z[S] + z[\overline{S}]$

Null space property

Defn. For $x \in \mathbb{R}^n$ let $supp(x) = \{j \le n \mid x_j \ne 0\}$

Defn. $\mathsf{NSP}_s(A) \equiv$

 $\left| \forall S \subseteq [n] \ \left(|S| = s \ \rightarrow \ \forall y \in \mathsf{N}^0_A \ \|y[S]\|_1 < \overline{\|y[\bar{S}]\|_1} \right) \right|$

A has the null space property of order s

Significance: $Ax = b \to A(x + y) = b$ for every $y \in \mathsf{N}^0_A$ $\Rightarrow y \in \mathsf{N}^0_A$ has smaller ℓ_1 norm value from y[S] than $y[\bar{S}]$

- We show that A has the NSP of order s is the same as every s-sparse x^* is the unique optimum of $P^1(A, Ax^*)$
- ▶ **Prop.** $\mathsf{NSP}_s(A) \Leftrightarrow$ $\forall x^* \in \mathbb{R}^n \; (|\mathsf{supp}(x^*)| \le s \to x^* = \operatorname{uniq} P^1(A, Ax^*))$

the "NSP proposition"

Strength of NSP_t as t grows

NSP Prop. states $|supp(x^*)| \leq s$ but $NSP_s(A)$ assumes |S| = s: why?

Lemma

 $\forall A \in \mathbb{R}^{m \times n}, t < s < n \quad \mathsf{NSP}_s(A) \Rightarrow \mathsf{NSP}_t(A)$ Proof $\mathsf{NSP}_s(A) \equiv \forall S \subseteq [n] \ (|S| = s \to \forall y \in \mathsf{N}^0_A \ \|y[S]\|_1 < \|y[\bar{S}]\|_1), \text{ hence:}$ given $T, U \subseteq [n]$ with T, U nontrivial disjoint, |T| = t and $|T \cup U| = s$, • $\forall y \in \mathbb{N}_4^0 \|y[T \cup U]\|_1 < \|y[\overline{T \cup U}]\|_1 = \|y[[n] \setminus (T \cup U)]\|_1 \Rightarrow$ (†) $\forall y \in \mathbb{N}_{4}^{0} \|y[T]\|_{1} + \|y[U]\|_{1} < \|y\|_{1} - \|y[T]\|_{1} - \|y[U]\|_{1} \Rightarrow$ (‡) $\forall y \in \mathsf{N}_{4}^{0} ||y[T]||_{1} < ||y[\bar{T}]||_{1} - 2||y[U]||_{1}$ whence $\forall T \subseteq [n] \ (|T| = t \rightarrow \forall y \in \mathsf{N}^0_A \|y[T]\|_1 < \|y[\bar{T}]\|_1)$ since $||y[U]||_1 > 0$, and so $\mathsf{NSP}_t(A)$ $\|y[T \cup U]\|_1 = \sum_{j \in T \cup U} |y_j| = \sum_{j \in T} |y_j| + \sum_{j \in U} |y_j| = \|y[T]\|_1 + \|y[U]\|_1$ (†) $\|y[[n] \setminus V]\|_1 = \sum_{j \in [n] \setminus V} |y_j| = \sum_{j \in [n]} |y_j| - \sum_{j \in V} |y_j| = \|y\|_1 - \|y[V]\|_1$

(‡) $\|y\|_1 - \|y[T]\|_1 = \sum_{j \le n} |y_j| - \sum_{j \in T} |y_j| = \sum_{j \notin T} |y_j| = \sum_{j \in \bar{T}} |y_j| = \|y_j[\bar{T}]\|_1$

Proof of the NSP proposition (\Rightarrow)

 $\forall x^*(|\mathsf{supp}(x^*)| \!=\! s \to x^* \!=\! \operatorname{uniq} P^1(A, Ax^*)) \Rightarrow \mathsf{NSP}_s(A)$

- ▶ <u>Claim</u> $\forall y \in \mathbb{N}^0_A$ and $S \subseteq [n]$ with |S| = s we have $Ay[S] \neq 0$ $Pf. \ y[S]$ has $|\mathsf{supp}(x)| = s$, by hyp y[S] uniq min of $P^1(A, Ay[S])$; if Ay[S] = 0 then **0** solves $P^1(A, Ay[S])$ and $\|\mathbf{0}\|_1 < \|y[S]\|_1$ contradicting min, so $Ay[S] \neq 0$
- ▶ $\forall y \in \mathbb{R}^n$ and $S \subseteq [n]$ we have $y = y[S] + y[\overline{S}]$
- ► ⇒ for any $y \in \mathsf{N}^0_A$ we have $Ay = Ay[S] + Ay[\bar{S}] = 0$ ⇒ $A(-y[\bar{S}]) = Ay[S] \neq 0$ by claim

• Therefore, $-y[\bar{S}]$ is feasible in $P^1(A, Ay[S])$

▶ $y[S] \neq -y[\overline{S}]$ othw by $y = y[S] + y[\overline{S}]$ both would be scalings of y and hence both in N_A^0 , which cannot happen as $Ay[S] \neq 0$

$$\begin{split} \bullet & \|y[S]\|_1 \text{ uniq min value and } -y[\bar{S}] \text{ feas in } P^1(A, Ay[S]) \Rightarrow \\ & \|-y[\bar{S}]\|_1 = \|y[\bar{S}]\|_1 > \|y[S]\|_1 \Rightarrow \mathsf{NSP}_s(A) \end{split}$$

Proof of the NSP proposition (\Leftarrow) $NSP_s(A) \Rightarrow \forall x^*(|supp(x^*)| = s \rightarrow x^* = uniq P^1(A, Ax^*))$ • Let $x^* \in \mathbb{R}^n$, $b = Ax^*$, $S = \operatorname{supp}(x^*)$ and |S| = s• Let \bar{x} soln. of Ax = b, then $\bar{x} = x^* - y$ with $y \in N^0_A$ [add and subtract same qty] $||x^*||_1 = ||(x^* - \bar{x}[S]) + \bar{x}[S]||_1$ [by triangle inequality] < $||x^* - \bar{x}[S]||_1 + ||\bar{x}[S]||_1$ $[S = \text{supp}(x^*) \Rightarrow x^* = x^*[S]] = \|x^*[S] - \bar{x}[S]\|_1 + \|\bar{x}[S]\|_1$ [since $x^* - \bar{x} = y$] = $\|y[S]\|_1 + \|\bar{x}[S]\|_1$ [since $y \in \mathbb{N}^0_A$ and $\mathbb{NSP}_s(A)$ holds] $\langle \|y[\bar{S}]\|_1 + \|\bar{x}[S]\|_1$ [since $y = x^* - \bar{x}$ and $x^*[\bar{S}] = 0$] = $\| - \bar{x}[\bar{S}] \|_1 + \| \bar{x}[S] \|_1$ [since $||-z||_1 = ||z||_1 \wedge z[S] + z[\bar{S}] = z$] = $||\bar{x}||_1$ $\Rightarrow \|x^*\|_1 < \|\bar{x}\|_1$

if x^* min of $P^1(A, Ax^*)$ and any other feas \overline{x} not a min $\Rightarrow x^*$ uniq min

A variant of the null space property

- ▶ Motivation: "almost sparse solutions" given \hat{x} with $|\operatorname{supp}(\hat{x})| > s$ and $b = A\hat{x}$ let $S = \underset{T \subseteq [n]:|T|=s}{\operatorname{arg\,max}} \|\hat{x}[T]\|_1$ and $\bar{x} = \hat{x}[S] (\Rightarrow |\operatorname{supp}(\bar{x})| = s)$
- Assume $\|\hat{x}[\bar{S}]\|_1 \ll \|\hat{x}[S]\|_1$ and $\epsilon = \max_{j \in \bar{S}} |\hat{x}_j|$ is small \hat{x} "almost" has support size s: all nonzeroes in $\hat{x}[\bar{S}]$ are "almost zero" ($\leq \epsilon$)
- Show min x^* of $P^1(A, A\hat{x})$ is s-sparse and close to \hat{x}
- Generalize NSP with $\rho \in (0, 1)$: $\mathsf{NSP}_s^{\rho}(A) \Leftrightarrow \forall S \subseteq [n] \ (|S| = s \to \forall y \in \mathsf{N}_A^0 \| y[S] \|_1 \le \rho \| y[\bar{S}] \|_1)$
- ▶ **Prop.** $\mathsf{NSP}_s^{\rho}(A) \Rightarrow \text{if } x^* \min \text{ of } P^1(A, A\hat{x}) \text{ then}$ $\|x^* - \hat{x}\|_1 \le 2\frac{1+\rho}{1-\rho} \|\bar{x} - \hat{x}\|_1 \le (n-s)\epsilon$

i.e. x^* is a good approximation of \bar{x}

• Moreover, if $|\mathsf{supp}(\hat{x})| = s$ then $x^* = \hat{x} = \bar{x}$

Proof of the NSP_s^{ρ} proposition

► x^* feasible in $Ax = A\hat{x}$ so $\exists ! y \in \mathsf{N}_A \ (x^* = \hat{x} + y)$

 $\blacktriangleright \Rightarrow \|x^*\|_1 = \|\hat{x} + y\|_1 \le \|\hat{x}\|_1 \text{ since } x^* \text{ min of } P^1(A, A\hat{x}) \ (\ddagger)$

$$\begin{aligned} \|\hat{x} + y\|_1 &= \sum_{j \in S} |\hat{x}_j + y_j| + \sum_{j \in \bar{S}} |\hat{x}_j + y_j| \\ &\geq \sum_{j \in S} (|\hat{x}_j| - |y_j|) + \sum_{j \in \bar{S}} (|y_j| - |\hat{x}_j|) \text{ by triangle ineq} \end{aligned}$$

- $$\begin{split} \bullet &= \|\hat{x}[S]\|_{1} \|y[S]\|_{1} + \|y[\bar{S}]\|_{1} \|\hat{x}[\bar{S}]\|_{1} \quad (\text{add and subtract } \|\hat{x}[\bar{S}]\|_{1} \Rightarrow) \\ &= \|\hat{x}\|_{1} 2\|\hat{x}[\bar{S}]\|_{1} + \|y[\bar{S}]\|_{1} \|y[S]\|_{1} \quad (\text{since } \bar{x} = \hat{x}[S] \Rightarrow) \\ &= \|\hat{x}\|_{1} 2\|\hat{x} \bar{x}\|_{1} + \|y[\bar{S}]\|_{1} \|y[S]\|_{1} \quad (*) \end{split}$$
- ► Therefore $(*) \leq \|\hat{x} + y\|_1 \leq \|\hat{x}\|_1$ by (‡), whence $\|\hat{x}\|_1 \geq \|\hat{x}\|_1 - 2\|\hat{x} - \bar{x}\|_1 + \|y[\bar{S}]\|_1 - \|y[S]\|_1$ (cancel $\|\hat{x}\|_1 \Rightarrow$) $2\|\hat{x} - \bar{x}\|_1 \geq \|y[\bar{S}]\|_1 - \|y[S]\|_1$
- ► By NSP_{s}^{ρ} , $-\|y[S]\|_{1} \ge -\rho\|y[\bar{S}]\|_{1}$, so $2\|\hat{x} - \bar{x}\|_{1} \ge (1 - \rho)\|y[\bar{S}]\|_{1}$ whence $\|y[\bar{S}]\|_{1} \le \frac{2}{1-\rho}\|\hat{x} - \bar{x}\|_{1}$ (†)

$$\begin{array}{l} \bullet \quad x^* = \hat{x} + y \Rightarrow \|x^* - \hat{x}\|_1 = \|y\|_1 = \|y[S]\|_1 + \|y[\bar{S}]\|_1 \\ \text{by } \mathsf{NSP}_s^{\rho} \|y[S]\|_1 \le \rho \|y[\bar{S}]\|_1 \text{ hence } \|x^* - \hat{x}\|_1 \le (1+\rho)\|y[\bar{S}]\|_1 \\ \text{by } (\dagger) \ \|x^* - \hat{x}\|_1 \le 2\frac{1+\rho}{1-\rho}\|\hat{x} - \bar{x}\|_1 \\ \end{array}$$

• Further, $\|\hat{x} - \bar{x}\|_1 = \|\hat{x} - \hat{x}[S]\|_1 = \|\hat{x}[\bar{S}]\| \le |\bar{S}|\epsilon = (n-s)\epsilon$

Restricted isometry property

• A is an $m \times n$ matrix, $\delta \in (0, 1), s \in \mathbb{N}$

- ► $\mathsf{RIP}_s^{\delta}(A) \iff \forall x \in \mathbb{R}^n \text{ s.t. } |\mathsf{supp}(x)| = s \text{ we have}$ $(1 - \delta) ||x||_2^2 \le ||Ax||_2^2 \le (1 + \delta) ||x||_2^2$
- ▶ **Prop.** $\mathsf{RIP}_{2s}^{\delta}(A) \land \rho = \frac{\sqrt{2\delta}}{1-\delta} < 1 \Rightarrow \mathsf{NSP}_{s}^{\rho}(A)$ See Thm. 5.12 in [Damelin & Miller 2012] for a proof
- It suffices that $\delta < \sqrt{2} 1 \approx 0.4142$

RIP and $P^0(A, b)$

• Recall $P^0(A, b) \equiv \min\{||x||_0 \mid Ax = b\}$ is NP-hard find solution to Ax = b with smallest support size

▶ Thm. Let $\hat{x} \in \mathbb{R}^n$ with $|\mathsf{supp}(\hat{x})| = s, \delta < 1, A$ a matrix s.t. $\mathsf{RIP}_{2s}^{\delta}(A), x^* \in \arg P^0(A, A\hat{x})$; then $x^* = \hat{x}$

Pf. Suppose false, let $y = x^* - \hat{x} \neq 0$; by define of x^* we have $||x^*||_0 \leq ||\hat{x}||_0 \leq s$, hence $||y||_0 \leq 2s$; since A has RIP get $||Ay||_2^2 \in (1 \pm \delta) ||y||_2^2$, but $Ay = Ax^* - A\hat{x} = 0$ while $y \neq 0$, and $\delta \in (0, 1) \rightarrow 1 \pm \delta > 0$, hence $0 \in (\alpha, \beta)$ where $\alpha, \beta > 0$, contradiction

Thm. 23.6 [Shwartz & Ben-David, 2014]

Result of limited scope, since we don't know if $P^0(A, b)$ can be solved efficiently if A has the RIP

Sufficient eigenvalue conditions for RIP

- Recall $\operatorname{RIP}_{s}^{\delta}(A)$: $\forall x \text{ with } S = \operatorname{supp}(x) \text{ and } |S| = s$ $(1 - \delta) \|x\|_{2}^{2} \le \|Ax\|_{2}^{2} \le (1 + \delta) \|x\|_{2}^{2}$
- Let $A^J = (A^j \mid j \in J)$, where A^j is the *j*-th col. of A
- $\|Ax\|_2^2 = \langle Ax, Ax \rangle = \langle A^S x[S], A^S x[S] \rangle = \langle B_S x[S], x[S] \rangle$ where $B_S = (A^S)^\top A^S$ is $s \times s$ and PSD, and consider x[S] as a vector in \mathbb{R}^s
- $\Rightarrow 0 \le \lambda_{\min}(B_S) \|x\|_2^2 \le \langle B_S x, x \rangle \le \lambda_{\max}(B_S) \|x\|_2^2$ replace B_S by its spectral decomp $P \Lambda P^{\top}$, note $\Lambda = \operatorname{diag}(\lambda_{\min}, \dots, \lambda_{\max})$

• Let
$$\lambda^L = \min_{|S|=s} \lambda_{\min}(B_S), \ \lambda^U = \max_{|S|=s} \lambda_{\max}(B_S)$$

► $\Leftarrow \exists \delta > 0 \text{ s.t. } 1 - \delta \leq \lambda^L \leq \lambda^U \leq 1 + \delta$ *i.e.* all eigenvalues of B(S) close to 1 for all $S \subset [n]$ with |S| = s

Construction of A s.t. $\mathsf{RIP}_s^{\delta}(A)$

- ▶ Need $\lambda \approx 1$ for each eigenvalue λ of B_S
- $\blacktriangleright \Rightarrow \text{Need} \quad \forall S \subseteq N \quad |S| = s \ \rightarrow \ (A^S)^\top A^S \approx I_s$

 $\blacktriangleright \Rightarrow \text{Need}$

$$\forall i < j \le n \quad (A^i)^\top A^j \approx 0 \forall i \le n \quad (A^i)^\top A^i = \|A^i\|_2^2 \approx 1$$

Sufficient condition: A sampled from $N(0, \frac{1}{\sqrt{m}})^{mn}$

▶ Difference with JLL RIP holds for uncountably many vectors x with |supp(x)| = sJLL holds for given sets of finitely many vectors with any support

Project idea 8: What other types of rectangular matrices M have the property $M^{\top}M = I$ or $\approx I$? Can they be used to prove the main theorem? How do they work, computationally, compared with matrices sampled from normal distributions? Compare on at least 50 random instances of $P^1(A, b)$

Isotropic vectors

- 1. **Defn.** Rnd vect $a \in \mathbb{R}^m$ is *isotropic* iff $\operatorname{cov}(a) = I_m$ remark: (a) $\operatorname{cov}(a) = \mathsf{E}(aa^{\top})$; (b) if $a \sim \mathsf{N}(0, 1)^m$ then a isotropic
- 2. If rnd vect *a* isotropic, then $\forall x \in \mathbb{R}^m \mathsf{E}(\langle a, x \rangle^2) = ||x||_2^2$ For two sq. symm. matrices *B*, *C* we have *B* = *C* iff $\forall x (x^\top Bx = x^\top Cx)$; hence $\mathsf{E}(\langle a, x \rangle^2) = x^\top \mathsf{E}(aa^\top)x = x^\top I_m x = ||x||_2^2$
- 3. If rnd vect $a \in \mathbb{R}^m$ isotropic, then $\mathsf{E}(||a||_2^2) = m$ $\mathsf{E}(||a||_2^2) = \mathsf{E}(a^\top a) = \mathsf{E}(\mathsf{tr}(a^\top a)) = \mathsf{E}(\mathsf{tr}(aa^\top)) = \mathsf{tr}(\mathsf{E}(aa^\top)) = \mathsf{tr}(I_m) = m$
- If rnd vect a, c ∈ ℝ^m indep. isotropic, then E(⟨a, c⟩²) = m By conditional expectation E(⟨a, c⟩²) = E_c(E_a(⟨a, c⟩² | c)); by Item 2 inner expectation is ||c||²₂, by Item 3 outer is m
- 5. If $a \sim N(0, 1)^m$, $||a||_2 = O(\sqrt{m})$ wahp by Thm. 3.1.1 in [Vershynin, 2018]
- 6. Independent rnd vectors are almost orthogonal Results above $\Rightarrow ||a||_2, ||c||_2, \langle a, c \rangle = O(\sqrt{m})$, normalize a, c to \bar{a}, \bar{c} to get $\langle \bar{a}, \bar{c} \rangle = O(1/\sqrt{m}) \Rightarrow$ for m large $\langle \bar{a}, \bar{c} \rangle \approx 0$

Construction of A s.t. $\mathsf{RIP}^{\delta}_{s}(A)$

▶ Thm. For $A \sim \mathsf{N}(0, 1)^{m \times n}$ and $\delta \in (0, 1) \exists C_1, C_2 > 0$ depending on δ s.t.

$$\forall s < m \left(m \geq \frac{s \ln(n/s)}{C_1} \rightarrow \mathsf{Prob}(\mathsf{RIP}^\delta_s(A)) \geq 1 - e^{-C_2 m} \right)$$

Pf. see Thm. 5.17 in [Damelin & Miller, 2012]

Remark: extra \sqrt{m} factor in A comes from $\|\cdot\|_2 \leq \|\cdot\|_1 \leq \sqrt{m}\|\cdot\|_2$

▶ In practice:

• $\mathsf{Prob}(\mathsf{RIP}^{\delta}_{s}(A)) = 0$ for m too small w.r.t. s fixed

► as *m* increases $\mathsf{Prob}(\mathsf{RIP}_s^{\delta}(A)) > 0$

- ► as *m* increases even more $\mathsf{Prob}(\mathsf{RIP}^{\delta}_{s}(A)) \to 1$ wahp
- \blacktriangleright achieve logarithmic compression for large n and fixed s
- $A \sim \mathsf{N}(0,1)^{mn} \wedge m \ge 10s \ln \frac{n}{s} \Rightarrow \mathsf{RIP}_s^{1/3}(A)$ wahp Lem. 5.5.2 [Moitra 2018]
- works better than worst case bounds ensured by theory

Subsection 4

Application to noisy channel encoding

Noisy channel encoding procedure Algorithm:

- 1. message: character string μ
- 2. $w = \text{string2bitlist}(\mu) \in \{0, 1\}^d$
- 3. send z = Qw, receive $\bar{z} = z + \hat{x}$, let $b = A\bar{z}$

 $\Delta = s/n = density of \hat{x}, \quad Q \text{ is } n \times d \text{ full rank with } n > d$

4.
$$x^* \in \arg P^1(A, b)$$

5. $z^* = \bar{z} - x^*$

6. $w^* = \operatorname{cap}(\operatorname{round}((Q^\top Q)^{-1}Q^\top z^*), [0, 1])$ $\operatorname{cap}(t, [\alpha, \beta]) = (\alpha \text{ if } t < \alpha) \text{ xor } (\beta \text{ if } t > \beta) \text{ xor } (t \text{ othw})$

7. $\mu^* = \text{bitlist2string}(w^*)$

8. evaluate $\mu_{\mathsf{err}} = \|\mu - \mu^*\|$

Parameter choice [Matousek]:

- $\blacktriangleright \text{ noise } \Delta = 0.08$
- redundancy n = R d, where R = 4

Finding orthogonal A, Q

▶ [Matousek, Gärtner 2007]:

▶ sample A componentwise from N(0, 1)

• then "find Q s.t. QA = 0"

• Gaussian elim. on underdetermined system AQ = 0

► Faster:

- sample n × n matrix M from uniform distr full rank with probability 1
- ▶ find eigenvector matrix of $M^{\top}M$ (orthonormal basis) random rotation of standard basis (used in original JLL proof)
- Concatenate d eigenvectors to make Q Concatenate m = n - d eigenvectors to make A AQ = 0 by construction!

Subsection 5

Improvements

LP size reduction

► Motivation

▶ Reduce CPU time spent on LP

▶ R = 4 redundancy for $\Delta = 0.08$ noise seems excessive

▶ Size of basis pursuit LP

- Ax = b is an $m \times n$ system where m = n d
- If $n = Rd \gg d$, *m* "relatively close" to *n*
- ► Use random projections for LP

Computational results

Reducing redundancy in n

- How about taking $n = (1 + \Delta)d$?
- ▶ $m = n d \approx \Delta d$ is very small
- Makes Ax = b very short and fat
- Prevents compressed sensing from working correctly not enough constraints
- Would need both m and d to be $\approx n$ and AQ = 0: impossible

 \mathbb{R}^n too small to host $m + d \approx 2n$ orthogonal vectors

▶ Relax to $AQ \approx 0$?

Almost orthogonality by the JLL Aim at A^{\top}, Q with $m + d \approx 2n$ and $AQ \approx 0$

▶ JLL Corollary: $\exists O(e^k)$ approx orthog vectors in \mathbb{R}^k Pf. Let *T* be a $k \times p$ RP, use concentration of measure on $||z||_2^2$ Prob $((1-\varepsilon)||z||_2^2 \leq ||Tz||_2^2 \leq (1+\varepsilon)||z||_2^2) \geq 1 - 2e^{-\mathcal{C}(\varepsilon^2 - \varepsilon^3)k}$

given $x, y \in \mathbb{R}^p$ apply to x + y, x - y and union bound:

$$\begin{aligned} |\langle Tx, Ty \rangle - \langle x, y \rangle| &= \frac{1}{4} \Big| ||T(x+y)||^2 - ||T(x-y)||^2 - ||x+y||^2 + ||x-y||^2 \Big| \\ &\leq \frac{1}{4} \Big| ||T(x+y)||^2 - ||x+y||^2 \Big| + \frac{1}{4} \Big| ||T(x-y)||^2 - ||x-y||^2 \Big| \\ &\leq \frac{\varepsilon}{4} (||x+y||^2 + ||x-y||^2) = \frac{\varepsilon}{2} (||x||^2 + ||y||^2) \end{aligned}$$

with prob $\geq 1 - 4e^{-\mathcal{C}(\varepsilon^2 - \varepsilon^3)k}$; apply to std basis matrix I_p , get

$$-\varepsilon \leq \langle T\mathbf{e}_i, T\mathbf{e}_j \rangle - \langle \mathbf{e}_i, \mathbf{e}_j \rangle \leq \varepsilon$$

 $\Rightarrow \exists p \text{ almost orthogonal vectors in } \mathbb{R}^k, \text{ and } k = O(\frac{1}{\varepsilon^2} \ln p) \Rightarrow p = O(e^k)$

• Algorithm: $k = n, p = \lceil e^n \rceil$, get 2k columns from $T I_p$

Also see [https://terrytao.wordpress.com/2013/07/18/ a-cheap-version-of-the-kabatjanskii-levenstein-bound-for-almost-orthogonal-vectors/]

Almost orthogonality by the JLL

- Aim at $m \times n A$ and $n \times m Q$ s.t. $AQ \approx 0$ with $n = (1 + \Delta')m$ and Δ' "small" (say $\Delta' < 1$)
- ▶ Need 2m approx orthog vectors in \mathbb{R}^n with n < 2m
- Computationally: get large ||AQ||₂
 JLL theory requires exceedingly large sizes to work well
- ▶ JLL ⇒ orthog row(A) and col(Q)but we only need AQ = 0!can accept non-orthogonality in rows of A & cols of Q
Almost orthogonality by LP

▶ Sample Q and compute A using an LP

$$\max \sum_{\substack{i \le m \\ j \le n}} \mathsf{Uniform}(-1,1)A_{ij}$$

• subject to AQ = 0 and $A \in [-1, 1]$

• for m = 328 and n = 590 (i.e. $\Delta' = 0.8$):

• error:
$$\sum A_i Q^j = O(10^{-10})$$

- **rank**: full up to error precision (*not really though*)
- ► CPU: 688s (*meh*)

• for m = 328 and n = 492 (i.e. $\Delta' = 0.5$): the same

- for m = 328 and n = 426 (i.e. $\Delta' = 0.3$): *CPU* 470s
- Reduce CPU time by solving m LPs deciding A_i for all $i \leq m$

Computational results

m	n	Δ'	$\mu_{\rm err}^{\rm org}$	μ_{err}^{prj}	CPU^{org}	CPU^{prj}
328	426	0.3	182	15	2.45	1.87
			154	0	2.20	1.49
	459	0.4	0	1	4.47	2.45
			5	17	2.86	1.46
	492	0.5	60	0	4.53	1.18
			34	0	5.38	1.18
	590	0.8	14	0	8.30	1.41
			107	4	6.76	1.43

 CPU for computing A, Q not counted: can pre-compute them (valid for most messages)
 Approximate beats precise!

In summary

• If μ is short, set $\Delta' = \Delta$ and use compressed sensing (CS)

• If μ is longer, try increasing Δ' and use CS

• If μ is very long, use *JLL-projected CS*

 \blacktriangleright Can use approximately orthogonal A, Q too

m = 1896, n = 2465 $\Delta' = 0.3$: min s.t. CS is accurate

Conticuere omnes, intentique ora tenebant. Inde toro pater Aeneas sic orsus ab alto: Infandum, regina, iubes renovare dolorem. Troianas ut opes et lamentabile regnum eruerint Danai Quaequae ipse miserrima vidi et quorum pars magna fui. [Virgil, Aeneid, Cantus II]

 CS
 0
 29.67s

 JLL-CS
 2
 17.13s

These results are consistent over 3 samplings

Project idea 9: Implement and test RPs applied to CS, as described in the last slides. Aim at setting the redundancy n equal to the noise $(1 + \Delta)d$, and use CPLEX to compute A such that $AQ \approx 0$. Test your code on at least 10 different texts of various lengths, up to around 500 characters. How does decoding quality depend on $||AQ||_2$?

Definition

- ▶ Optimization version. Given $K \in \mathbb{N}$, determine the maximum number kn(K) of unit spheres that can be placed adjacent to a central unit sphere so their interiors do not overlap
- ▶ Decision version. Given $n, K \in \mathbb{N}$, is $kn(K) \leq n$? in other words, determine whether n unit spheres can be placed adjacent to a central unit sphere so that their interiors do not overlap

Funny story: Newton and Gregory went down the pub...

Some examples

Radius formulation

Given $n, K \in \mathbb{N}$, determine whether there exist n vectors $x_1, \ldots, x_n \in \mathbb{R}^K$ such that:

$$\forall i \le n \qquad \|x_i\|_2^2 = 4$$

$$\forall i < j \le n \qquad \|x_i - x_j\|_2^2 \ge 4$$

Contact point formulation

Given $n, K \in \mathbb{N}$, determine whether there exist n vectors $x_1, \ldots, x_n \in \mathbb{R}^K$ such that:

$$\begin{aligned} \forall i \leq n & \|x_i\|_2^2 &= 1 \\ \forall i < j \leq n & \|x_i - x_j\|_2^2 &\geq 1 \end{aligned}$$

Spherical codes

▶ $S^{K-1} \subset \mathbb{R}^K$ unit sphere centered at origin

► *K*-dimensional spherical *z*-code:

- (finite) subset $\mathcal{C} \subset S^{K-1}$
- $\blacktriangleright \quad \forall x \neq y \in \mathcal{C} \qquad x \cdot y \leq z$

▶ non-overlapping interiors:

$$\forall i < j \quad \|x_i - x_j\|_2^2 \geq 1 \Leftrightarrow \quad \|x_i\|_2^2 + \|x_j\|_2^2 - 2x_i \cdot x_j \geq 1 \\ \Leftrightarrow \quad 1 + 1 - 2x_i \cdot x_j \geq 1 \\ \Leftrightarrow \quad 2x_i \cdot x_j \leq 1 \\ \Leftrightarrow \quad x_i \cdot x_j \leq \frac{1}{2} = \cos\left(\frac{\pi}{3}\right) = z$$

► we aim at maximizing $kn_z(K) \triangleq |\mathcal{C}|$ let $kn(K) = kn_{\frac{1}{2}}(K)$

Subsection 1

Lower bounds

Lower bounds

- Construct spherical $\frac{1}{2}$ -code \mathcal{C} with $|\mathcal{C}|$ large
- ▶ Nonconvex NLP formulations
- ▶ SDP relaxations
- Combination of the two techniques

MINLP formulation

Maculan, Michelon, Smith 1995

Parameters:

- \blacktriangleright K: space dimension
- ▶ *n*: upper bound to kn(K)

Variables:

- $x_i \in \mathbb{R}^K$: contact pt. of *i*-th surrounding sphere
- $\alpha_i = 1$ iff sphere *i* in configuration

$$\begin{array}{rcl} \max & \sum_{i=1}^{n} \alpha_i \\ \forall i \leq n & ||x_i||^2 &= \alpha_i \\ \forall i < j \leq n & ||x_i - x_j||^2 &\geq \alpha_i \alpha_j \\ \forall i \leq n & x_i &\in [-1, 1]^K \\ \forall i \leq n & \alpha_i &\in \{0, 1\} \end{array}$$

Reformulating the binary products

- Additional variables: $\beta_{ij} = 1$ iff vectors i, j in configuration
- ► Linearize $\alpha_i \alpha_j$ by β_{ij}
- ► Add constraints:

$$\begin{aligned} \forall i < j \leq n & \beta_{ij} \leq \alpha_i \\ \forall i < j \leq n & \beta_{ij} \leq \alpha_j \\ \forall i < j \leq n & \beta_{ij} \geq \alpha_i + \alpha_j - 1 \end{aligned}$$

Computational experiments

AMPL and Baron

Certifying YES

•
$$n = 6, K = 2$$
: OK, 0.60s

▶
$$n = 12, K = 3$$
: OK, 0.07s

▶ n = 24, K = 4: FAIL, CPU time limit (100s)

Certifying NO

▶
$$n = 7, K = 2$$
: FAIL, CPU time limit (100s)

▶
$$n = 13, K = 3$$
: FAIL, CPU time limit (100s)

▶ n = 25, K = 4: FAIL, CPU time limit (100s)

Almost useless

Modelling the decision problem

$$\left. \begin{array}{ccc} \max_{x,\alpha} & \alpha \\ \forall i \leq n & ||x_i||^2 &= 1 \\ \forall i < j \leq n & ||x_i - x_j||^2 \geq \alpha \\ \forall i \leq n & x_i \in [-1,1]^K \\ \alpha \geq 0 \end{array} \right\}$$

[Kucherenko, Belotti, Liberti, Maculan, Discr. Appl. Math. 2007]

Computational experiments AMPL and Baron

Certifying YES

Certifying NO

▶ n = 13, K = 3: FAIL, CPU time limit (100s)

Apparently even more useless

But more informative $(\arccos \alpha = \min. \text{ angular sep})$

Certifying YES by $\alpha \geq 1$

- ▶ n = 6, K = 2: OK, 0.06s
- n = 12, K = 3: OK, 0.05s
- ▶ n = 24, K = 4: OK, 1.48s

▶ n = 40, K = 5: FAIL, CPU time limit (100s)

What about polar coordinates?

$$\begin{array}{rcl} (\dagger) & \forall k \leq K \quad \rho \sin \vartheta_{i,k-1} \prod_{h=k}^{K-1} \cos \vartheta_{ih} & = & x_{ik} \\ (\dagger) & \forall i < j \leq n \quad \|x_i - x_j\|_2^2 & \geq & \rho^2 \\ \forall i \leq n, k \leq K \quad (\sin(\vartheta_{ik}))^2 + (\cos(\vartheta_{ik}))^2 & = & 1 \\ & (optional) & \rho & = & 1 \end{array}$$

- Only need to decide $s_{ik} = \sin \vartheta_{ik}$ and $c_{ik} = \cos \vartheta_{ik}$
- Replace x in (‡) using (†): get polyprog in s, c

 $\blacktriangleright Numerically more challenging to solve (polydeg 2K)$

▶ OPEN QUESTION: useful for bounds?

Subsection 2

Upper bounds from SDP?

SDP relaxation of Euclidean distances

Linearization of scalar products

$$\forall i, j \le n \qquad x_i \cdot x_j \longrightarrow X_{ij}$$

where X is an $n \times n$ symmetric matrix

 $||x_i||_2^2 = x_i \cdot x_i = X_{ii}$ $||x_i - x_j||_2^2 = ||x_i||_2^2 + ||x_j||_2^2 - 2x_i \cdot x_j = X_{ii} + X_{jj} - 2X_{ij}$ $||X_i - x_j||_2^2 = ||x_i||_2^2 + ||x_j||_2^2 - 2x_i \cdot x_j = X_{ii} + X_{jj} - 2X_{ij}$ $||X_i - x_j||_2^2 = ||x_i||_2^2 + ||x_j||_2^2 - 2x_i \cdot x_j = X_{ii} + X_{jj} - 2X_{ij}$ $||X_i - x_j||_2^2 = ||x_i||_2^2 + ||x_j||_2^2 - 2x_i \cdot x_j = X_{ii} + X_{jj} - 2X_{ij}$ ||X_i - x_j||_2^2 = ||x_i||_2^2 + ||x_j||_2^2 - 2x_i \cdot x_j = X_{ii} + X_{jj} - 2X_{ij} ||X_i - x_j||_2^2 = ||x_i||_2^2 + ||x_j||_2^2 - 2x_i \cdot x_j = X_{ii} + X_{jj} - 2X_{ij} ||X_i - x_j||_2^2 = ||x_i||_2^2 + ||x_j||_2^2 - 2x_i \cdot x_j = X_{ii} + X_{jj} - 2X_{ij} ||X_i - x_j||_2^2 = ||x_i||_2^2 + ||x_j||_2^2 - 2x_i \cdot x_j = X_{ii} + X_{jj} - 2X_{ij}||X_i - x_j||_2^2 = ||x_i||_2^2 + ||x_j||_2^2 - 2x_i \cdot x_j = X_{ii} + X_{jj} - 2X_{ij}||X_i - x_j||_2^2 = ||x_i||_2^2 + ||x_j||_2^2 - 2x_i \cdot x_j = X_{ii} + X_{jj} - 2X_{ij}||X_i - x_j||_2^2 = ||x_i||_2^2 + ||x_j||_2^2 - 2x_i \cdot x_j = X_{ii} + X_{jj} - 2X_{ij}||X_i - x_j||_2^2 = ||x_i||_2^2 + ||x_j||_2^2 - 2x_i \cdot x_j = X_{ii} + X_{ij} - 2X_{ij}||X_i - x_j||_2^2 = ||x_i||_2^2 + ||x_j||_2^2 - 2x_i \cdot x_j = X_{ii} + X_{ij} - 2X_{ij}||X_i - x_j||_2^2 = ||x_i||_2^2 + ||x_j||_2^2 - 2x_i \cdot x_j = X_{ij} + X_{ij} +

$$X - xx^{\top} \succeq 0 \Rightarrow \mathsf{Schur}(X, x) = \begin{pmatrix} I_K & x^{\top} \\ x & X \end{pmatrix} \succeq 0$$

SDP relaxation of binary constraints

- $\blacktriangleright \quad \forall i \le n \qquad \alpha_i \in \{0,1\} \Leftrightarrow \alpha_i^2 = \alpha_i$
- Let A be an $n \times n$ symmetric matrix
- Linearize $\alpha_i \alpha_j$ by A_{ij} (hence α_i^2 by A_{ii})
- $A = \alpha \alpha^{\top}$ makes linearization exact
- **Relaxation:** Schur $(A, \alpha) \succeq 0$

SDP relaxation of [MMS95]

Computational experiments

- Python, PICOS and Mosek or Octave and SDPT3
- \blacktriangleright bound always equal to n
- ▶ prominent failure :-(
- ► Why?

▶ can combine inequalities to remove A from SDP

$$\forall i < j \; X_{ii} + X_{jj} - 2X_{ij} \geq A_{ij} \geq \alpha_i + \alpha_i - 1 \Rightarrow X_{ii} + X_{jj} - 2X_{ij} \geq \alpha_i + \alpha_i - 1$$

(then eliminate all constraints in A)

• integrality of α completely lost

SDP relaxation of [KBLM07]

Computational experiments

With K = 2

Computational experiments

With K = 3

Always $\longrightarrow 2?$

An SDP-based heuristic?

- 1. $X^* \in \mathbb{R}^{n^2}$: SDP relaxation solution of [KBLM07]
- 2. Perform PCA, get $\bar{x} \in \mathbb{R}^{nK}$
- 3. Local NLP solver on [KBLM07] with starting point \bar{x}

However...

The Uselessness Theorem

Thm.

- 1. The SDP relaxation of [KBLM07] is useless
- 2. In fact, it is *extremely* useless
- 1. Part 1: Uselessness
 - ► Independent of K:

no useful bounds in function of K

- 2. Part 2: Extreme uselessness
 - (a) For all n, the bound is $\frac{2n}{n-1}$

(b) $\exists opt. X^* with eigenvalues 0, \frac{n}{n-1}, \dots, \frac{n}{n-1}$

By 2(b), applying MDS/PCA makes no sense

Proof of extreme uselessness

Strategy:

- ▶ Pull a simple matrix solution out of a hat
- ▶ Write primal and dual SDP of [KBLM07]
- ▶ Show it is feasible in both
- ▶ Hence it is optimal
- ► Analyse solution:
 - ▶ all n-1 positive eigenvalues are equal
 - its objective function value is 2n/(n-1)

Primal SDP

$\forall 1 \leq i \leq j \leq n \text{ let } B_{ij} = (1_{ij}) \text{ and } 0 \text{ elsewhere}$

quantifier	natural form	standard form	$dual \ var$
	$\max \alpha$	$\max \alpha$	
$\forall i \leq n$	$X_{ii} = 1$	$E_{ii} \bullet X = 1$	u_i
$\forall i < j \leq n$	$X_{ii} + X_{jj} - 2X_{ij} \ge \alpha$	$A_{ij} \bullet X + \alpha \le 0$	w_{ij}
		$A_{ij} = -E_{ii} - E_{jj} + E_{ij} + E_{ji}$	
$\forall i < j \le n$	$X_{ij} \le 1$	$(E_{ij} + E_{ji}) \bullet X \le 2$	y_{ij}
$\forall i < j \le n$	$X_{ij} \ge -1$	$(-E_{ij} - E_{ji}) \bullet X \le 2$	z_{ij}
	$X \succeq 0$	$X \succeq 0$	
	$\alpha \ge 0$	$lpha \ge 0$	

Dual SDP

$$\min \sum_{i} u_i + 2 \sum_{i < j} (y_{ij} + z_{ij})$$
$$\sum_{i} u_i E_{ii} + \sum_{i < j} ((y_{ij} - z_{ij})(E_{ij} - E_{ji}) + w_{ij}A_{ij}) \succeq 0$$
$$\sum_{i < j} w_{ij} \geq 1$$
$$w, y, z \ge 0$$

Simplify |v| = y + z, v = y - z:

$$\min \sum_{i} u_i + 2 \sum_{i < j} |v_{ij}|$$

$$\sum_{i} u_i E_{ii} + \sum_{i < j} \left(v_{ij} (E_{ij} - E_{ji}) + w_{ij} A_{ij} \right) \succeq 0$$

$$\sum_{i < j} w_{ij} \geq 1$$

$$w, v \ge 0$$

Pulling a solution out of a hat

$$\alpha^* = \frac{2n}{n-1}$$

$$X^* = \frac{n}{n-1}I_n - \frac{1}{n-1}\mathbf{1}_n$$

$$u^* = \frac{2}{n-1}$$

$$w^* = \frac{1}{n(n-1)}$$

$$v^* = 0$$

where
$$\mathbf{1}_n = all$$
-one $n \times n$ matrix

Solution verification

- ▶ linear constraints: *by inspection*
- $X \succeq 0$: eigenvalues of X^* are $0, \frac{n}{n-1}, \ldots, \frac{n}{n-1}$

 $\blacktriangleright \sum_{i} u_i E_{ii} + \sum_{i < j} (v_{ij}(E_{ij} - E_{ji}) + w_{ij}A_{ij}) \succeq 0:$

Corollary

$$\lim_{n \to \infty} \mathbf{v}(n, [\text{KBLM07}]) = \lim_{n \to \infty} \frac{2n}{n-1} = 2$$

as observed in computational experiments

Subsection 3

Gregory's upper bound

Surface upper bound

Gregory 1694, Szpiro 2003

Consider a kn(3) configuration inscribed into a super-sphere of radius 3. Imagine a lamp at the centre of the central sphere that casts shadows of the surrounding balls onto the inside surface of the super-sphere. Each shadow has a surface area of 7.6; the total surface of the super-ball is 113.1. So $\frac{113.1}{7.6} = 14.9$ is an upper bound to kn(3).

At end of XVII century, yielded Newton/Gregory dispute

Subsection 4

Delsarte's upper bound
Pair distribution on sphere surface

▶ Spherical z-code C has $x_i \cdot x_j \leq z$ $(i < j \leq n = |C|)$

$$\forall t \in [-1,1] \quad \sigma_t = \frac{1}{n} \big| \{(i,j) \mid i,j \le n \land x_i \cdot x_j = t\} \big|$$

z-code: let σ_t = 0 for t ∈ (z, 1) (z = 1/2 for KNP)
 |C| = n < ∞: only finitely many σ_t ≠ 0

$$\int_{[-1,1]} \sigma_t dt = \sum_{\substack{t \in [-1,1]\\\sigma_t \neq 0}} \sigma_t = \frac{1}{n} |\text{all pairs}| = \frac{n^2}{n} = n$$
$$\sigma_1 = \frac{1}{n}n = 1$$
$$\forall t \in (z,1) \quad \sigma_t = 0$$
$$\forall t \in [-1,1] \quad \sigma_t \ge 0$$
$$|\{\sigma_t > 0 \mid t \in [-1,1]\}| < \infty$$

Growing Delsarte's LP

- Decision variables: σ_t , for $t \in [-1, 1]$
- ► Objective function:

$$\max |\mathcal{C}| = \max n = \max_{\sigma} \sum_{\substack{t \in [-1,1] \\ \sigma_t \neq 0}} \sigma_t$$
$$= \sigma_1 + \max_{\sigma} \sum_{\substack{t \in [-1,z] \\ \sigma_t \neq 0}} \sigma_t = 1 + \max_{\sigma} \sum_{\substack{t \in [-1,z] \\ \sigma_t \neq 0}} \sigma_t$$

Note n not a parameter in this formulation

► Constraints:

 $\forall t \in [-1, z] \quad \sigma_t \ge 0$

▶ LP unbounded! — need more constraints

The general approach

• We need σ to encode the fact that

$$\forall t \in [-1,1] \quad \sigma_t = \frac{1}{n} \big| \{(i,j) \mid i,j \le n \land x_i \cdot x_j = t\} \big|$$

▶ We use the algebraic theory in [Delsarte et al., "Spherical codes and designs", *Geometriæ Dedicata* 6:363-388, 1977]

▶ It involves the expression of a non-negative polynomial by means of a linear combination of Gegenbauer polynomials weighted by the σ_t

I will skip over the details

▶ You can also see the proof in [Odlyzko, Sloane, "New bounds on the number of unit spheres that can touch a unit sphere in *n* dimensions", J. of Comb. Theory A, 26:210-214, 1979]

Gegenbauer cuts

• Look for function family $\mathscr{F} : [-1,1] \to \mathbb{R}$ s.t.

$$\forall \phi \in \mathscr{F} \quad \sum_{\substack{t \in [-1,1]\\\sigma_t \neq 0}} \phi(t) \sigma_t \ge 0$$

Most popular 𝔅: Gegenbauer polynomials G^K_h
 Special case G^K_h = P^{γ,γ}_h of Jacobi polynomials (where γ = (K − 2)/2)

$$P_{h}^{\alpha,\beta}(t) = \frac{1}{2^{h}} \sum_{i=0}^{h} \binom{h+\alpha}{i} \binom{h+\beta}{h-1} (t+1)^{i} (t-1)^{h-i}$$

- ▶ Matlab knows them: G^K_h(t) = gegenbauerC(h, (K − 2)/2, t)
 ▶ Octave knows them: G^K_h(t) = gsl_sf_gegenpoly_n(h, K−2/2, t) need command pkg load gsl before function call
- **They encode dependence on** *K*

Delsarte's LP

Primal: (given some Gegenbauer polynomial index set H)

$$\begin{array}{ccc} 1 + \max & \sum\limits_{\substack{t \in [-1, \frac{1}{2}] \\ \sigma_t \neq 0}} \sigma_t \\ \forall h \in H & \sum\limits_{\substack{t \in [-1, \frac{1}{2}] \\ \sigma_t \neq 0}} G_h^K(t) \sigma_t \geq -G_h^K(1) \\ \forall t \in [-1, z] & \sigma_t \geq 0. \end{array} \right\} [\text{DelP}]$$

MP syntax error: decision variables σ in sum quantifier! Dual:

$$\begin{array}{rcl}
1 + \min & \sum_{h \in H} (-G_h^K(1))d_h \\
\forall t \in [-1, z] & \sum_{h \in H} G_h^K(t)d_h \geq 1 \\
\forall h \in H & d_h \leq 0.
\end{array}$$
[DelD]

Delsarte's theorem

 $\begin{array}{l} \hline \text{[Delsarte et al., 1977; Odlyzko \& Sloane, 1979]} \\ \hline \textbf{Theorem} \\ Let $d \in \mathbb{R}_+^\ell$ with $d_0 > 0$, and $F: [-1,1] \rightarrow \mathbb{R}$ s.t.: $(i) \quad \forall t \in [-1,1] \quad F(t) = \sum\limits_{h \leq \ell} d_h G_h^K(t) $ $(ii) \quad \forall t \in [-1,z] \quad F(t) \leq 0$ $Then $ \mathsf{kn}_z(K) \leq \frac{F(1)}{d_0}$ } \end{array}$

Proof based on properties of Gegenbauer polynomials

- ▶ Best upper bound: $\min F(1)/d_0 \Rightarrow \min_{d_0=1} F(1) \Rightarrow [\text{DelD}]$
- ▶ [DelD] "models" Delsarte's theorem (take $\ell = |H|$)

Delsarte's normalized LP $(G_h^K(1) = 1)$ \blacktriangleright Primal:

$$\begin{array}{ccc} 1 + \max & \sum_{\substack{t \in [-1, \frac{1}{2}] \\ \sigma_t \neq 0 \\ \sigma_t \neq 0 \\ \forall t \in [-1, \frac{1}{2}] \\ \forall t \in [-1, \frac{1}{2}] \end{array} \sigma_t} \sigma_t & \geq & -1 \\ \end{array} \right\} [\text{DelP}]$$

$$\begin{array}{ccc} 1 + \min & \sum_{h \in H} (-1)d_h \\ \forall t \in [-1, \frac{1}{2}] & \sum_{h \in H} G_h^K(t)d_h \geq 1 \\ \forall h \in H & d_h \leq 0 \end{array} \right\} [\text{DelD}]$$

 $d_0 = 1 \Rightarrow remove \ 0 \ from \ H$

Focus on normalized [DelD]

Rewrite $-d_h$ as d_h :

$$\begin{array}{ccc} 1 + \min & \sum_{h \in H} d_h \\ \forall t \in [-1, \frac{1}{2}] & \sum_{h \in H} G_h^K(t) d_h &\leq -1 \\ \forall h \in H & d_h &\geq 0 \end{array} \right\} [\text{DelD}]$$

Issue: semi-infinite LP (SILP) (how do we solve it?)

Approximate SILP solution

► Only keep finitely many constraints

- ▶ Discretize [-1, 1] with a finite $T \subset [-1, 1]$
- Obtain <u>relaxation</u> $[DelD]_T$:

$\mathsf{val}([\mathrm{DelD}]_T) \le \mathsf{val}([\mathrm{DelD}])$

• Risk: val($[DelD]_T$) < min $F(1)/d_0$

not a valid upper bound to $kn_z(K)$

▶ Happens if soln. of $[DelD]_T$ infeasible in [DelD]i.e. infeasible w.r.t. some of the ∞ly many removed constraints

SILP feasibility

• Given SILP $\bar{S} \equiv \min\{c^{\top}x \mid \forall t \in \bar{T} \langle a(t), x \rangle \leq b(t)\}$

- ▶ Relax to LP $S \equiv \min\{c^{\top}x \mid \forall t \in T \ \langle a(t), x \rangle \leq b(t)\}$ with $T \subsetneq \overline{T}$ and $|T| < \infty$
- ► Solve S, get solution x^*

$$Let \ \epsilon = \max_t \{ \langle a(t), x^* \rangle - b(t) \mid t \in \overline{T} \}$$

$$continuous \ NLP \ with \ a \ single \ var. \ t$$

- ► If $\epsilon \leq 0$ then x^* feasible in \bar{S} ⇒ $\operatorname{val}(\bar{S}) \leq c^\top x^*$
- If $\epsilon > 0$ refine S and repeat

• Apply to $[DelD]_T$, get solution d^* feasible in [DelD]

[DelD] feasibility

- 1. Choose discretization T of [-1, z]
- 2. Solve $\begin{array}{cccc}
 1 + \min & \sum_{h \in H} d_h \\
 \forall t \in T & \sum_{h \in H} G_h^K(t) d_h &\leq -1 \\
 \forall h \in H & d_h &\geq 0
 \end{array}
 \right\} [\text{DelD}]_T$

get solution d^*

- 3. Solve PP $\epsilon = \max_t \{1 + \sum_{h \in H} G_h^K(t) d_h^* \mid t \in [-1, z]\}$
- 4. If $\epsilon \leq 0$ then d^* feasible in [DelD] $\Rightarrow \operatorname{kn}_z(K) \leq 1 + \sum_{h \in H} d_h^*$

5. Else refine T and repeat from Step 2

Subsection 5

Pfender's upper bound

Pfender's upper bound theorem

Thm. Let $\mathcal{C}_z = \{x_i \in \mathbb{S}^{K-1} \mid i \leq n \land \forall j \neq i \ (x_i \cdot x_j \leq z)\}; c_0 > 0; f : [-1,1] \rightarrow \mathbb{R} \text{ s.t.}:$ (i) $\sum f(x_i \cdot x_j) \ge 0$ (ii) $f(t) + c_0 \le 0$ for $t \in [-1, z]$ (iii) $f(1) + c_0 \le 1$ $i \overline{i < n}$ Then $\operatorname{\mathsf{kn}}_z(K) = n \leq \frac{1}{c_0}$ ([Pfender 2006]) Let $q(t) = f(t) + c_0$ $n^2 c_0 \leq n^2 c_0 + \sum f(x_i \cdot x_j)$ by (i) $i, j \leq n$ $= \sum (f(x_i \cdot x_j) + c_0) = \sum g(x_i \cdot x_j)$ $i,j \leq n$ $i,j \leq n$ $\leq \sum g(x_i \cdot x_i)$ since $g(t) \leq 0$ for $t \leq z$ and $x_i \in \mathcal{C}_z$ for $i \leq n$ $i \leq n$ = ng(1) since $||x_i||_2 = 1$ for $i \leq n$ $\leq n$ since $q(1) \leq 1$.

Pfender's LP

 Condition (i) of Theorem valid for conic combinations of suitable functions F:

$$f(t) = \sum_{h \in H} c_h f_h(t)$$
 where $c_h \ge 0$ for $h \in H$,

e.g. $\mathcal{F} =$ Gegenbauer polynomials (again)

▶ Get SILP

$$\max_{\substack{c \in \mathbb{R}^{|H|} \\ e \in \mathbb{R}^{|H|}}} c_0 \qquad (\text{minimize } 1/c_0 \ge n)$$

$$\forall t \in [-1, z] \qquad \sum_{\substack{h \in H \\ h \in H}} c_h G_h^K(t) + c_0 \le 0 \quad (\text{ii})$$

$$\sum_{\substack{h \in H \\ h \in H}} c_h G_h^K(1) + c_0 \le 1 \quad (\text{iii})$$

$$\forall h \in H \qquad c_h \ge 0 \quad (\text{conic comb.})$$

• Discretize [-1, z] by finite T, solve LP, check validity (again)

Delsarte's and Pfender's theorem compared

Delsarte & Pfender's theorem look similar:

Delsarte	Pfender
(i) $F(t)$ G. poly comb	(i) $f(t)$ G. poly comb
(ii) $\forall t \in [-1, z] F(t) \leq 0$	(ii) $\forall t \in [-1, z] f(t) + c_0 \le 0$
	(iii) $f(1) + c_0 \le 1$
$\Rightarrow \operatorname{kn}_{z}(K) \leq \frac{F(1)}{d_{0}}$	$\Rightarrow \operatorname{kn}_z(K) \leq \frac{1}{c_0}$

Try setting $F(t) = f(t) + c_0$: condition (ii) is the same

▶ By condition (iii) in Pfender's theorem

$$\mathsf{kn}_z(K) \le \frac{F(1)}{d_0} = \frac{f(1) + c_0}{c_0} \le \frac{1}{c_0}$$

 \Rightarrow Delsarte bound at least as tight as Pfender's

▶ Delsarte (i) $\Rightarrow \int_{[-1,1]} F(t) dt \ge 0 \Rightarrow \int_{[-1,1]} (f(t) + c_0) dt \ge 0$ Pfender (i) $\Rightarrow \int_{[-1,1]} f(t) dt \ge 0$ more stringent

If \mathcal{F} are Gegenbauer polynomials, Delsarte requires weaker condition and yields tighter bound; but Pfender allows for more general \mathcal{F} , can get improved results see [Pfender, "Improved Delsarte bounds for spherical codes in small dimensions", J. Comb. Theory A, 114:1133-1147, 2007]

The final, easy improvement

▶ However you compute your upper bound B:
▶ The number of surrounding balls is *integer*▶ If kn_z(K) ≤ B, then in fact kn_z(K) ≤ LB

A typical job offer

Under the responsibility of the Commercial Director, the Optimisation / Operations Senior Manager will have the responsibility to optimise and develop operational aspects for VINCI Airports current and future portfolio of airports. They will also be responsible for driving forward and managing key optimisation projects that assist the Commercial Director in delivering the objectives of the Technical Services Agreements activities of VINCI Airports. The Optimisation Manager will support the Commercial Director in the development and implementation of plans, strategies and reporting processes. As part of the exercise of its function, the Optimisation Manager will undertake the following: Identification and development of cross asset synergies with a specific focus on the operations and processing functions of the airport. Definition and implementation of the Optimisation Strategy in line with the objectives of the various technical services agreements, the strategy of the individual airports and the Group. This function will include: Participation in the definition of airport strategy. Definition of this airport strategy into the Optimisation Strategy, Regularly evaluate the impact of the Optimisation Strategy. Ensure accurate implementation of this strategy at all airports. Management of the various technical services agreements with our airports by developing specific technical competences from the Head Office level. Oversee the management and definition of all optimisation projects. Identification, overview and management of the project managers responsible for the delivery of the various optimization projects at each asset. Construction of good relationships with the key stakeholders, in order to contribute to the success of each optimization project. Development and implementation of the Group optimisation plan. Definition of economic and quality of service criteria, in order to define performance goals. Evaluation of the performance of the Group operations in terms of processing efficiency, service levels, passenger convenience and harmonization of the non-aeronautical activities. Monitoring the strategies, trends and best practices of the airport industry and other reference industries in terms of the applicability to the optimization plan. Study of the needs and preferences of the passengers, through a continuous process of marketing research at all of the airports within the VINCI Airports portfolio. Development of benchmarking studies in order to evaluate the trends, in international airports or in the local market. Development and participation in the expansion or refurbishment projects of the airports, to assure a correct configuration and positioning of the operational and commercial area that can allow the optimization of the revenues and operational efficiency. Support the Director Business Development through the analysis and opportunity assessment of areas of optimization for all target assets in all bids and the preparation and implementation of the strategic plan once the assets are acquired. Maintain up to date knowledge of market trends and key initiatives related to the operational and commercial aspects of international airports [...]

 \ldots and blah blah blah: Is this appropriate for my CV?

358 / 413

Rationalizing the application process

- ▶ You collect many offers
- Don't have time to tailor application to each offer
- ▶ Partition offers into groups: clustering
- Need a similarity relation given two offers, do they describe "similar jobs"?
- ► Try Natural Language Processing (NatLangProc):
 - Automated summary
 - Relation Extraction
 - ► Named Entity Recognition (NER)
 - ► Keywords

Automated summary ./summarize.py job01.txt

They will also be responsible for driving forward and managing key optimisation projects that assist the Commercial Director in delivering the objectives of the Technical Services Agreements activities of VINCI Airports. The Optimisation Manager will support the Commercial Director in the development and implementation of plans, strategies and reporting processes. Identification and development of cross asset synergies with a specific focus on the operations and processing functions of the airport. Construction of good relationships with the key stakeholders, in order to contribute to the success of each optimization project. Definition of economic and quality of service criteria, in order to define performance goals. Evaluation of the performance of the Group operations in terms of processing efficiency, service levels, passenger convenience and harmonization of the non-aeronautical activities. Development of benchmarking studies in order to evaluate the trends, in international airports or in the local market. Maintain up to date knowledge of market trends and key initiatives related to the operational and commercial aspects of international airports. You have a diverse range of experiences working at or with airports across various disciplines such as operations, ground handling, commercial, etc. Demonstrated high level conceptual thinking, creativity and analytical skills.

Word similarity: WordNet

WordNet example: hyponyms of "boat"

Wu-Palmer word similarity

Semantic WordNet similarity between words w_1, w_2 :

$$\mathsf{wup}(w_1, w_2) = \frac{2 \operatorname{depth}(\mathsf{lca}(w_1, w_2))}{\mathsf{len}(\mathsf{shpath}(w_1, w_2)) + 2 \operatorname{depth}(\mathsf{lca}(w_1, w_2))}$$

- Ica: lowest common ancestor earliest common word in paths from both words to WordNet root
- depth: length of path from root to word

Example: wup(dog, boat)?

lca(dog, boat) = whole; depth(whole) = 4

18 -> dog -> canine -> carnivore -> placental -> mammal -> vertebrate -> chordate -> animal -> organism -> living_thing -> whole -> artifact -> instrumentality -> conveyance -> vehicle -> craft -> vessel -> boat

13 -> dog -> domestic_animal -> animal -> organism -> living_thing -> whole -> artifact -> instrumentality -> conveyance -> vehicle -> craft -> vessel -> boat

wup(dog, boat) = 8/21 = 0.380952380952

Extensions of Wu-Palmer similarity

 \blacktriangleright to lists of words H, L:

$$\mathsf{wup}(H,L) = \frac{1}{|H|\,|L|} \sum_{v \in H} \sum_{w \in L} \mathsf{wup}(v,w)$$

• to pairs of documents D_1, D_2 :

 $\mathsf{wup}(D_1, D_2) = \mathsf{wup}(\mathsf{NER}(D_1), \mathsf{NER}(D_2))$

The Wu-Palmer similarity matrix

The similarity graph

G = (V, E), weighted adjacency matrix A

Modularity clustering

"Modularity is the fraction of the edges that fall within a cluster minus the expected fraction if edges were distributed at random."

- *"at random"* = random graphs over same degree sequence
- degree sequence = (k_1, \ldots, k_n) where $k_i = |N(i)|$
- "expected" = over all possible "half-edge" recombinations degree sequence invariant operation

• expected edges between $u, v: k_u k_v / (2m)$ where m = |E|

$$\mathsf{mod}(u, v) = \frac{1}{2m} (A_{uv} - k_u k_v / (2m)) \text{ param}$$

$$\mathsf{mod}(G) = \sum_{\substack{\{u, v\} \in E \\ x_{uv} = 1 \text{ if } u, v \text{ in the same cluster and 0 otherwise}} \text{ var}$$

• "Natural extension" to weighted graphs: $k_u = \sum_v A_{uv}, m = \sum_{uv} A_{uv}$

Use modularity to define clustering

▶ What is the "best clustering"?

 Maximize discrepancy between actual and expected "as far away as possible from average"

$$\begin{array}{ll} \max & \sum_{\{u,v\}\in E} \mathsf{mod}(u,v) x_{uv} \\ \forall u \in V, v \in V \quad x_{uv} \in \{0,1\} \end{array}$$

- ▶ Issue: optimum could be intransitive
- ► Idea: treat clusters as cliques (even if zero weight) ⇒ clique partitioning constraints for transitivity

$$\begin{array}{rrrr} \forall i < j < k & x_{ij} + x_{jk} - x_{ik} & \leq & 1 \\ \forall i < j < k & x_{ij} - x_{jk} + x_{ik} & \leq & 1 \\ \forall i < j < k & -x_{ij} + x_{jk} + x_{ik} & \leq & 1 \end{array}$$

 $\textit{if } i,j \in C \textit{ and } j,k \in C \textit{ then } i,k \in C \\$

The resulting clustering

Is it good?

? — named entities rarely appear in WordNet
Desirable property: chooses number of clusters

Subsection 2

Clustering in Euclidean spaces

Clustering vectors

$\begin{array}{c} \textit{Most frequent words } \hline w \textit{ over collection } \hline C \textit{ of documents } d \\ \textit{./keywords.py} \end{array}$

global environment customers strategic processes teams sql job industry use java developing project process engineering field models opportunity drive results statistical based operational performance using mathematical computer new technical highly market company science role dynamic background products level methods design looking modeling manage learning service customer effectively technology requirements build mathematics problems plan services time scientist implementation large analytical techniques lead available plus technologies sas provide machine product functions organization algorithms position model order identify activities innovation key appropriate different complex best decision simulation strategy meet client assist quantitative finance commercial language mining travel chain amazon pricing practices cloud supply

$$\begin{aligned} \mathsf{tfidf}_C(w,d) &= \frac{|(t \in d \mid t = w)| \, |C|}{|\{h \in C \mid w \in h\}|} \\ \mathsf{keyword}_C(i,d) &= word \ w \ having \ i^{th} \ best \ \mathsf{tfidf}_C(w,d) value \\ \mathsf{vec}_C^m(d) &= (\mathsf{tfidf}_C(\mathsf{keyword}_C(i,d),d) \mid i \leq m) \end{aligned}$$

Transforms documents to vectors

tfidf: text frequency inverse document frequency

Minimum sum-of-squares clustering

- \blacktriangleright MSSC, a.k.a. the *k*-means problem
- Given points $p_1, \ldots, p_n \in \mathbb{R}^m$, find clusters C_1, \ldots, C_k

$$\min \sum_{j \le k} \sum_{i \in C_j} \|p_i - \mathsf{centroid}(C_j)\|_2^2$$

where centroid $(C_j) = \frac{1}{|C_j|} \sum_{i \in C_j} p_i$

▶ k-means alg.: given initial clustering C_1, \ldots, C_k

1: $\forall j \leq k$ compute $y_j = \operatorname{centroid}(C_j)$ 2: $\forall i \leq n, j \leq k$ if y_j is the closest centr. to p_i let $x_{ij} = 1$ else 0 3: $\forall j \leq k$ update $C_j \leftarrow \{p_i \mid x_{ij} = 1 \land i \leq n\}$ 4: repeat until stability

A fickle algorithm

We can't trust k-means: why?

383 / 413

Subsection 3

Distance instability

Nearest Neighbours

basic problem in data science

pattern recognition, computational geometry, machine learning, data compression, robotics, recommender systems, information retrieval, natural language processing and more

• Example: Used in Step 2 of k-means: assign points to closest centroid

[Cover & Hart 1967]

With random variables

- ► Consider 1-NN
- Let $\ell = |\mathcal{X}|$
- Let m be an abstract parameter to index symbols with In other words, reason about sequences for concreteness, think of m = n (dimensions)

- Distance function family $\{d^m : \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}_+\}_m$
- For each m:
 - ▶ random variable Z^m with some distribution over \mathbb{R}^n
 - ▶ for $i \leq \ell$, random var. X_i^m with some distrib. over \mathbb{R}^n
 - ► X_i^m iid w.r.t. i, Z^m independent of all X_i^m

$$\blacktriangleright D^m_{\min} = \min_{i \le \ell} d^m(Z^m, X^m_i)$$

$$\blacktriangleright D^m_{\max} = \max_{i \le \ell} d^m(Z^m, X^m_i)$$

Distance Instability Theorem

Let p > 0 be a constant just makes the proof more general, think of p = 1
If

 $\exists i \leq \ell \quad (d^m(Z^m, X^m_i))^p \text{ converges as } m \to \infty$ then, for any $\varepsilon > 0$,

closest and furthest point are at about the same distance

Note " $\exists i$ " suffices since $\forall m$ we have X_i^m iid w.r.t. i

[Beyer et al. 1999]

Distance Instability Theorem

Note " $\exists i$ " suffices since $\forall m$ we have X_i^m iid w.r.t. i

[Beyer et al. 1999]

Preliminary results

• <u>Lemma</u>. $\{B^m\}_m$ seq. of rnd. vars with finite variance and $\lim_{m \to \infty} \mathbb{E}(B^m) = b \wedge \lim_{m \to \infty} \mathsf{Var}(B^m) = 0$; then

 $\forall \varepsilon > 0 \ \lim_{m \to \infty} \mathbb{P}(\|B^m - b\| \le \varepsilon) = 1$

denoted $B^m \to_{\mathbb{P}} b$

- ▶ <u>Slutsky's theorem</u>. $\{B^m\}_m$ seq. of rnd. vars and g a continuous function; if $B^m \to_{\mathbb{P}} b$ and g(b) exists, then $g(B^m) \to_{\mathbb{P}} g(b)$
- ▶ <u>Corollary</u>. If $\{A^m\}_m, \{B^m\}_m$ seq. of rnd. vars. s.t. $A^m \to_{\mathbb{P}} a$ and $B^m \to_{\mathbb{P}} b \neq 0$ then $\frac{A^m}{B^m} \to_{\mathbb{P}} \frac{a}{b}$

Proof

3.
$$\mathbf{V}^m = (V_m \mid i \leq \ell) \rightarrow_{\mathbb{P}} \mathbf{1} \text{ (by iid)}$$

4. Slutsky's thm. $\Rightarrow \min(\mathbf{V}^m) \rightarrow_{\mathbb{P}} \min(\mathbf{1}) = 1$ similarly for max

5. Corollary
$$\Rightarrow \frac{\max(\mathbf{V}^m)}{\min(\mathbf{V}^m)} \to_{\mathbb{P}} 1$$

6.
$$\frac{D_{\max}^m}{D_{\min}^m} = \frac{\mu_m \max(\mathbf{V}^m)}{\mu_m \min(\mathbf{V}^m)} \to_{\mathbb{P}} 1$$

7. Result follows (defn. of $\rightarrow_{\mathbb{P}}$ and $D_{\max}^m \ge D_{\min}^m$)

A precision limit

- <u>Closest</u> and <u>farthest</u> point from z: can't be told apart unless precision $\leq \varepsilon$
- ▶ In algorithms, often want "closest"
- Hope of telling apart $\underline{\text{closest}}$ from $\underline{\text{second-closest}}$?

Loss of precision ε for $n \leq 10000$ Uniform(0,1)

$\mathsf{Exponential}(1)$

Normal(0,1)

Precision falls exponentially fast

Generates algorithmic instability

When it applies

- ▶ iid random variables from any distribution
- ▶ Particular forms of correlation e.g. $U_i \sim \text{Uniform}(0, \sqrt{i}), X_1 = U_1, X_i = U_i + (X_{i-1}/2)$ for i > 1
- ► Variance tending to zero e.g. $X_i \sim N(0, 1/i)$
- Discrete uniform distribution on *m*-dimensional hypercube for both data and query
- Computational experiments with k-means: instability already with n > 15

... and when it doesn't

- Complete linear dependence on all distributions can be reduced to NN in 1D
- Exact and approximate matching $query \ point = (or \approx) \ data \ point$
- Query point in a well-separated cluster in data
- Implicitly low dimensionality project; but NN must be stable in lower dim.

Subsection 4

MP formulations

Why?

▶ With k-means being so fast, why bother with MP?

► Principle:

changing an MP is easier than changing an algorithm

► Side constraints

e.g. clusters are spheres, or other shapes

Clustering subproblems

e.g. assign resources subject to optimal clustering

▶ MP delivers a bound

"can't do better than bound" guarantee

MP formulation

$\min_{x,y,s}$	$\sum_{i \le n} \sum_{j \le k} \ p_i - y_j\ _2^2 x_{ij}$,		
$\forall j \le k$	$\frac{1}{s_j} \sum_{i \le n} p_i x_{ij}$	=	y_j		
$\forall i \leq n$	$\sum_{j \leq k} x_{ij}$	=	1		(MSSC)
$\forall j \leq k$	$\sum_{i \le n}^{j=1} x_{ij}$	=	s_j	ĺ	(MSSC)
$\forall j \le k$	y_j	\in	\mathbb{R}^m		
	x	\in	$\{0,1\}^{nk}$		
	s	\in	\mathbb{N}^k	J	

MINLP: nonconvex terms; continuous, binary and integer variables

Reformulation

The (MSSC) formulation has the same optima as:

The only nonconvexities are products of binary by continuous <u>bounded</u> variables

Products of binary and continuous vars.

- Suppose term xy appears in a formulation
- Assume $x \in \{0, 1\}$ and $y \in [0, 1]$ is bounded
- means "either z = 0 or z = y"
- $\blacktriangleright Replace xy by a new variable z$
- ► Adjoin the following constraints:

$$z \in [0, 1]$$

$$y - (1 - x) \leq z \leq y + (1 - x)$$

$$-x \leq z \leq x$$

 \blacktriangleright \Rightarrow Everything's linear now!

[Fortet 1959]

Products of binary and continuous vars.

- Suppose term xy appears in a formulation
- Assume $x \in \{0, 1\}$ and $y \in [y^L, \overline{y^U}]$ is bounded
- means "either z = 0 or z = y"
- $\blacktriangleright Replace xy by a new variable z$
- ► Adjoin the following constraints:

$$z \in [\min(y^{L}, 0), \max(y^{U}, 0)]$$

$$y - (1 - x) \max(|y^{L}|, |y^{U}|) \leq z \leq y + (1 - x) \max(|y^{L}|, |y^{U}|)$$

$$-x \max(|y^{L}|, |y^{U}|) \leq z \leq x \max(|y^{L}|, |y^{U}|)$$

 \blacktriangleright \Rightarrow Everything's linear now!

[L. et al. 2009]

MSSC is a convex MINLP

$$\begin{split} \min_{\substack{x,y,P,\chi,\xi}} & \sum_{i \leq n} \sum_{j \leq k} \chi_{ij} \\ \forall i \leq n, j \leq k \quad 0 \leq \chi_{ij} \leq P_{ij} \\ \forall i \leq n, j \leq k \quad P_{ij} - (1 - x_{ij})P^U \leq \chi_{ij} \leq x_{ij}P^U \\ \forall i \leq n, j \leq k \quad \||p_i - y_j\||_2^2 \leq P_{ij} \quad \Leftarrow \text{ convex} \\ \forall j \leq k \quad \sum_{i \leq n} p_i x_{ij} = \sum_{i \leq n} \xi_{ij} \\ \forall i \leq n, j \leq k \quad y_j - (1 - x_{ij}) \max(|y^L|, |y^U|) \leq \xi_{ij} \leq y_j + (1 - x_{ij}) \max(|y^L|, |y^U|) \\ \forall i \leq n, j \leq k \quad -x_{ij} \max(|y^L|, |y^U|) \leq \xi_{ij} \leq x_{ij} \max(|y^L|, |y^U|) \\ \forall i \leq n, j \leq k \quad y_j \in [y^L, y^U] \\ & \chi \in \{0, 1\}^{nk} \\ P \in [0, P^U]^{nk} \\ & \chi \in [0, P^U]^{nk} \\ & \forall i \leq n, j \leq k \quad \xi_{ij} \in [\min(y^L, 0), \max(y^U, 0)] \end{split}$$

 y_j, ξ_{ij}, y^L, y^U are vectors in \mathbb{R}^m

How to solve it

- ▶ cMINLP is **NP**-hard
- ► Algorithms:
 - ► Outer Approximation (OA)
 - ► Branch-and-Bound (BB)
- ▶ Best (open source) solver: BONMIN
- ► Another good (commercial) solver: KNITRO
- With k = 2, unfortunately...

Cbc0010I After 8300 nodes, 3546 on tree, 14.864345 best solution, best possible 6.1855969 (32142.17 seconds)

► Interesting feature: the <u>bound</u>

guarantees we can't do better than *bound* all BB algorithms provide it

Couple of things left to try

Approximate l₂ by l₁ norm l₁ is a linearizable norm Randomly project the data

lose dimensions but keep approximate shape

Linearizing convexity

- ▶ Replace $||p_i y_j||_2^2$ by $||p_i y_j||_1$
- ▶ Warning: optima will change

but still within "clustering by distance" principle

$$\forall i \le n, j \le k \quad \|p_i - y_j\|_1 = \sum_{a \le d} |p_{ia} - y_{ja}|$$

- ▶ Replace each $|\cdot|$ term by new vars. $Q_{ija} \in [0, P^U]$ Adjust P^U in terms of $||\cdot||_1$
- Adjoin constraints

$$\begin{aligned} \forall i \leq n, j \leq k \quad \sum_{a \leq d} Q_{ija} &\leq P_{ij} \\ \forall i \leq n, j \leq k, a \leq d \quad -Q_{ija} &\leq p_{ia} - y_{ja} \leq Q_{ija} \end{aligned}$$

Obtain a MILP

MILP solver: use e.g. CPLEX

Subsection 5

Random projections again

Works on the MSSC MP formulation too!

$$\min_{\substack{x,y,s \\ i \leq n}} \sum_{i \leq n} \sum_{j \leq d} \|Tp_i - Ty_j\|_2^2 x_{ij}$$

$$\forall j \leq d \qquad \qquad \frac{1}{s_j} \sum_{i \leq n} Tp_i x_{ij} = Ty_j$$

$$\forall i \leq n \qquad \qquad \sum_{j \leq d} x_{ij} = 1$$

$$\forall j \leq d \qquad \qquad \sum_{i \leq n} x_{ij} = s_j$$

$$\forall j \leq d \qquad \qquad y_j \in \mathbb{R}^m$$

$$x \in \{0,1\}^{nd}$$

$$s \in \mathbb{N}^d$$

where T is a $k \times m$ random projector replace Ty by y'

Works on the MSSC MP formulation too!

(MSSC')

• where $k = O(\frac{1}{\varepsilon^2} \ln n)$

▶ less data, $|y'| < |y| \Rightarrow$ get solutions faster

Yields smaller cMINLP
